Patients with patellar tendon autografts are more prone to patellofemoral syndrome or patellar tendonitis than those with allografts or soft-tissue grafts. Dynamic exercises, such as plyometric work, put increasing stress on the patellar tendon, and anterior knee pain may become an issue during this phase. An infrapatellar strap, patellar taping, or patellofemoral brace may be of use, and programming may need to be adjusted.

Techniques for Progressive Increase in Range of Motion

- Self-performed range of motion stretching exercises should still be performed 4 to 5 times daily with an emphasis on maintaining the full passive extension and flexion that has been gained.

Other Therapeutic Exercises

- Continue to progress on flexibility and isometric strength work
- Stair stepper, NordicTrack, straight ahead running, or stationary bicycle to continue increasing endurance
- Advance closed chain exercises (see below)
- Advance hamstring exercises
- Advance balance/proprioceptive training (see below)

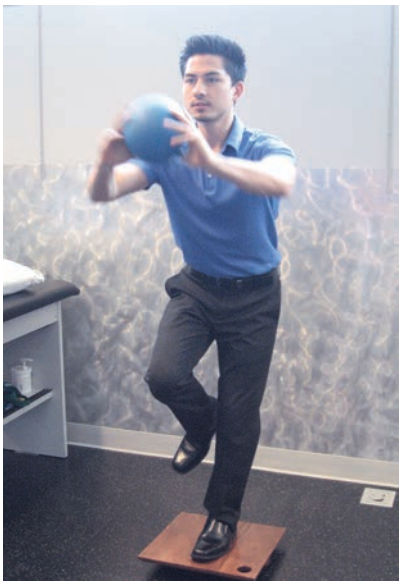

FIGURE 32-11. Single-leg balance training with medicine ball throws. This medicine ball exercise is performed while balancing on a tilt board with one leg.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Progress isometric strengthening program (quad and hamstring sets, straight leg raises, etc.)
- Hamstring curls and advanced hamstring exercises
- Continued progression of closed chain extension exercises (bilateral to unilateral, increasing resistance, increasing range of motion, etc.)

Sensorimotor Exercises

- Continue balance training on a tilt board and with medicine ball throws (Figure 32-11)
- Another advanced balance exercise is to have patient do a single-leg stance while reaching to cones on the floor or pulling a band laterally
- Progress unilateral perturbation training (Figure 32-12)

Open and Closed Kinetic Chain Exercises

- Lateral lunge step-overs
- Front and side lunges
- Lateral step-downs
- Front step-downs
- Wall squats
- Vertical squats
- Toe calf raises
- Stair stepper machine

Techniques to Increase Muscle Strength, Power, and Endurance

- Stair stepper/NordicTrack (Logan, UT)
- Bicycle
- Walking program
- Straight-line running

Neuromuscular Dynamic Stability Exercises

- Biodex stability system (Shirley, NY)
- Balance training on a tilt board and medicine ball throws (see Sensorimotor Exercises)
- Perturbation training

Plyometrics

- Initiate plyometric leg press and plyometric jumping exercises (Figure 32-13)
- Correct form as needed

Clinical Pearls

It is particularly important to observe landing mechanics during jumping exercises to reduce risk of recurrent injury. Things to watch for and correct include the following:

- Landing with low flexion angles (knee in too much extension)
- Landing with genu varum/valgum (watch for dynamic valgus)
- Landing and jumping with uninvolved limb dominating the effort

Functional Exercises

- Lunges with sport cord (Figure 32-14)
- Forward and backward running
- Jogging in place with sport cord
  - Can advance by pulling from various directions
- Pool running (backwards and forwards)

Sport-Specific Exercises

- Cone drills
- Side shuffles
- Grapevine drill
- Cariocas

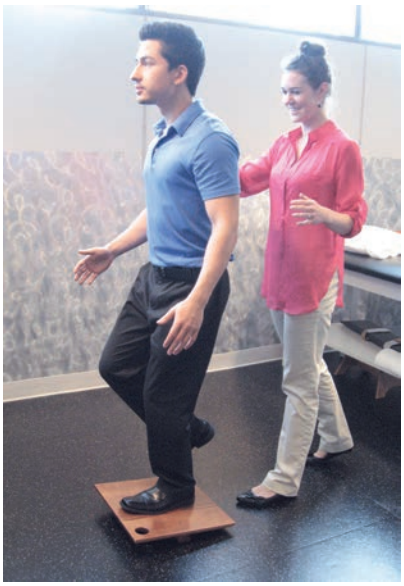

FIGURE 32-12. A–C, Single-leg perturbation training using a tilt board.

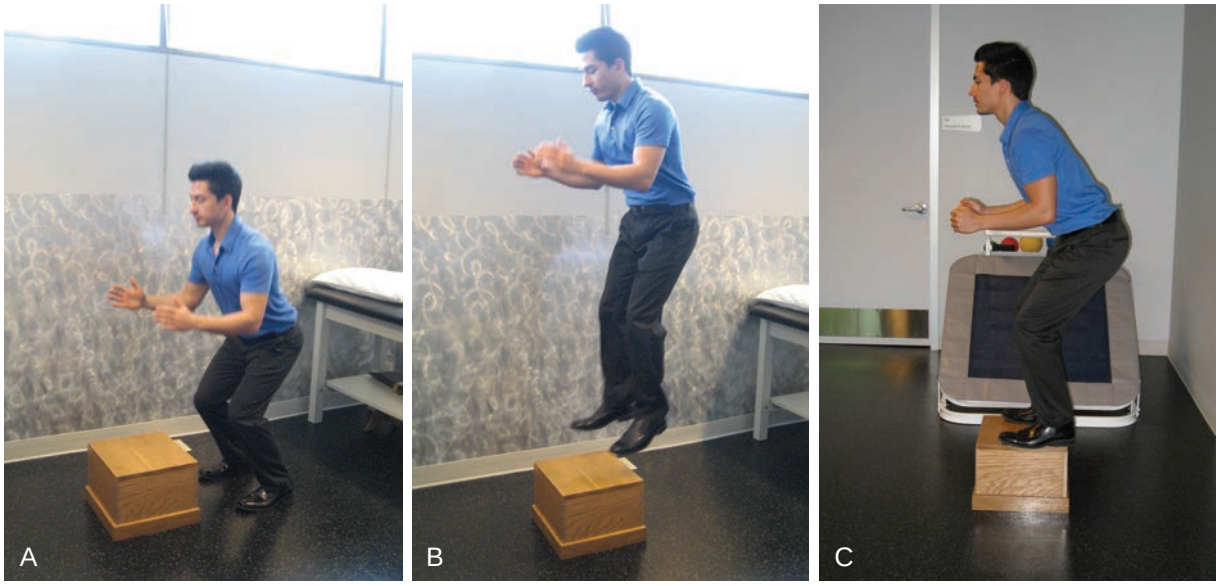

FIGURE 32-13. Plyometric jumping exercises.

- Sudden start/stops
- 45° cutting maneuvers
- 90° cutting maneuvers
- Combinations of agility drills
- Progress to sport-specific plyometric training drills
  - Hop variations, skipping and bounding variations, return to throwing program in overhead throwers, etc.

Milestones for Progression to the Next Phase

- Full range of motion
- Quiet knee (pain and effusion free)

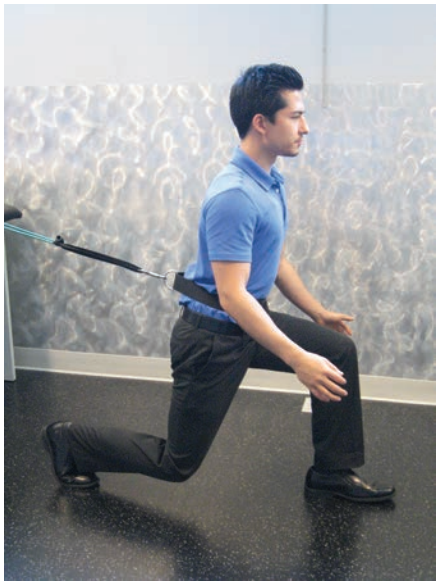

FIGURE 32-14. Lunges with sport cord.

- Quadriceps strength 80% or greater than opposite extremity
- Hamstring strength 110% or greater than opposite extremity
- Quadriceps torque/body weight ratio 55% or greater
- Hamstrings/quadriceps ratio 70% or greater
- Proprioceptive test equivalent to contralateral leg
- Return-to-sport testing/functional testing 85% or greater to contralateral leg

Phase V (months 6+)

Clinical Pearls

The overriding goal of Phase V is to return the patient back to their preinjury level of play, and building confidence in the reconstructed knee is a major factor in accomplishing this. Progressively increasing the difficulty level and applied loads in exercises and drills will help the patient achieve this. The workhorse exercises of this phase include single leg squats and lunges in addition to sport-specific drills.

Goals

- Gradual return to unrestricted sports
- Maximizing leg strength and endurance
- Normalizing neuromuscular control
- Progressing skill training
- Continuing to build limb confidence

Protection

- No more rehabilitative brace or crutches, although some patients may be using a functional brace at this point (e.g., football lineman, downhill skiers)

Management of Pain and Swelling

Treatment for pain/analgesia
- Pain should be minimal to absent at this point
- Cryotherapy, electrical stimulation, and transcutaneous electrical neuromuscular stimulation (TENS) devices can be used when necessary
- Narcotic pain medication should not be necessary at this point

Decrease swelling
- Joint compression with a knee sleeve or ace wrap are the most frequently used modalities
- Knee sleeve can be discontinued but some patients psychologically feel more comfortable when wearing it
- Ice for 20 minutes hourly and elevate lower extremity

Techniques for Progressive Increase in Range of Motion

- Self-performed range of motion stretching exercises should still be performed 4 to 5 times daily with an emphasis on maintaining the full passive extension and flexion that has been gained

Other Therapeutic Exercises

- Continue to progress on flexibility and isometric strength work
- Stair stepper, NordicTrack, straight ahead running, or stationary bicycle to continue increasing endurance
- Progression on closed chain exercises (see below)
- Progression on hamstring exercises
- Continue balance/proprioceptive training (see below)

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Hamstring curls and advanced hamstring exercises
- Leg press and squats
- Progress isometric strengthening program

Sensorimotor Exercises

- Continue balance training on a tilt board
- Continue balance training with medicine ball throws
- Continue perturbation training on single leg

Open and Closed Kinetic Chain Exercises

- Lateral lunge step-overs
- Front and side lunges
- Lateral step-downs
- Front step-downs
- Wall squats
- Vertical squats
- Toe calf raises
- Stair stepper machine

Techniques to Increase Muscle Strength, Power, and Endurance

- Stair stepper/NordicTrack
- Bicycle
- Walking program
- Straight-line running
- Advanced sport-specific endurance exercises (e.g., interval training)

Neuromuscular Dynamic Stability Exercises

- Biodex stability system
- Balance training on a tilt board
- Balance training with medicine ball throws
- Perturbation training

Plyometrics

- Can progress plyometric leg presses
- Continue other plyometric training drills

Functional Exercises

- Lunges with sport cord
- Forward and backward running
- Jogging in place with sport cord
  - Can advance by pulling from various directions
- Pool running (backward and forward)

Sport-Specific Exercises

- Cone drills
- Side shuffles
- Cariocas
- Sudden start/stop
- 45° cutting maneuvers
- 90° cutting maneuvers
- Combinations of agility drills
- Continue other plyometric training drills
- Sport- and position-specific skill training (e.g., coming out of a 3-point stance for football lineman, changing direction from backpedal to sprint, lateral mobility drills for linebackers, etc.).

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Athletes are encouraged to continue strength and agility exercises on their own to preserve strength, functional, and proprioceptive gains
- Female athletes may benefit from using an ACL prevention program for warmup before practice/games versus a traditional warmup. Compared to a traditional warm-up, these 15-minute programs emphasize posterior chain strength and proper plyometric landing mechanics.

Exercises and Other Techniques for Prevention of Recurrent Injury

- Lateral box jumps
- Single leg hurdles
- Single leg lunges and squats

Evidence

Krych AJ, Jackson JD, Hoskin TL, et al: A metaanalysis of patellar tendon autograft versus patellar tendon allograft in anterior cruciate ligament reconstruction. *Arthroscopy* 24:292–298, 2008.

This metaanalysis of 6 nonrandomized cohort studies compared the outcomes of 256 patients with patellar tendon autograft versus 278 patients with patellar tendon allograft. Overall, allografts had a higher rate of rupture (OR, 5.66;

p < .01) and allograft patients were more likely to have a hop test less than 90% of the nonoperative side (OR, 5.66; p < .01). When irradiated and chemically treated allografts were excluded from analysis, however, there were no significant differences in graft rupture, rate of reoperation, IKDC scores, Lachman exam, pivot shift exam, patellar crepitus, hop test, or return to sport. (Level III evidence)

Melegati G, Tornese D, Bandi M, et al: The role of the rehabilitation brace in restoring knee extension after anterior cruciate ligament reconstruction: A prospective controlled study. *Knee Surg Sports Traumatol Arthrosc* 11:322–326, 2003.

This randomized controlled trial compared 18 patients braced in extension for 1 week postoperatively (Group B) versus 18 patients braced from 0° to 90° (Group A). The braces were unlocked twice daily for physical therapy in the first week, unlocked at the beginning of week 2, and removed at the beginning of week 3. All participants followed the same accelerated rehabilitation protocol. Both groups had similar preoperative bubble-level heel height difference (HHD) measurements, and HHD measurements at 4 and 8 weeks showed significantly greater extension in the extension braced group (2.2 cm in Group A vs. 0.6 cm in Group B at week 4, 1.6 cm in Group A vs. 0.1 cm in Group B at week 8). There were no differences in KT-arthrometry at 4 months.

Risberg MA, Holm I, Myklebust G, et al: Neuromuscular training versus strength training during first 6 months after anterior cruciate ligament reconstruction: A randomized clinical trial. *Phys Ther* 87:737–750, 2007.

This randomized controlled trial compared the effect of 6 months of neuromuscular training (NT) to a traditional strength training program (ST) following ACL reconstruction in 74 patients. Both groups were evaulated preoperatively and at 3 and 6 months postoperatively. At the 6-month follow-up, the NT group had significantly improved Cincinnati knee scores and VAS scores for global knee function compared to the ST group. There were no significant differences for hop, balance, proprioception, and muscle strength tests. (Level I evidence)

Shelbourne KD, Gray T: Minimum 10-year results after anterior cruciate ligament reconstruction: How the loss of normal knee motion compounds other factors related to the development of osteoarthritis after surgery. *Am J Sports Med* 37:471–480, 2009.

This prospective cohort study evaluated the long-term subjective outcome after ACL reconstruction in 502 patients at a mean follow-up of 14.1 years. Regression analysis was then used to determine which factors affected subjective scores. The most statistically significant factor leading to a lower IKDC score was lack of normal extension, followed by loss of flexion. Normal knee motion was defined as within 2° of extension (including hyperextension) and 5° of flexion of the nonoperative knee. Patients with meniscectomy or articular cartilage procedures had statistically significantly lower subjective scores only if they also had less than normal range of motion. A total of 98% of patients with intact cartilage, normal knee motion, and intact menisci had normal radiographs; 29% of patients with normal range of motion had abnormal radiographs versus 71% with abnormal motion. IKDC score was normal in 48%, nearly normal in 42%, abnormal in 9%, and severely normal in 0.5%. The authors concluded that a loss of extension of 3° to 5° (including hyperextension) after ACL reconstruction adversely affected long-term subjective and objective outcomes, especially with concurrent meniscectomy or articular cartilage damage. (Level III evidence)

Yoo JH, Lim BO, Ha M, et al: A meta-analysis of the effect of neuromuscular training on the prevention of the anterior cruciate ligament injury in female athletes. *Knee Surg Sports Traumatol Arthrosc* 18:824–830, 2010.

This metaanalysis aimed to evaluate the effectiveness of neuromuscular training in preventing ACL injuries in female athletes, and to identify essential programming factors by subgroup analysis. Seven randomized controlled trials or prospective cohort studies were included in the analysis. Overall, the effect of a preventative training program in preventing ACL injury was found to be significant (OR 0.4, 95% CI 0.27–0.6). Age under 18, soccer (rather than handball), pre- and in-season preventative training (vs. pre- or in-season), and plyometrics and strengthening exercises (vs. balance exercises) were found to be significantly associated with program effectiveness. Metaanalysis showed that pre- and in-season neuromuscular training with an emphasis on plyometrics and strengthening was effective in preventing ACL injury in female athletes, especially in those under age 18.

Multiple-Choice Questions

QUESTION 1. At which milestone can bracing be discontinued?

A. At a predetermined time point (week 5)
B. After week 4 and when there is no longer an extension lag during SLR
C. When pain and swelling has become minimal
D. When there is 90° of passive flexion

QUESTION 2. Which of the following exercises should not be performed by week 5?

A. Partial ROM squats
B. Partial ROM leg presses
C. Hamstring curls
D. Quadriceps extensions

QUESTION 3. At which point should use of a functional brace be considered?

A. When starting closed chain extension exercises
B. At the onset of cutting and plyometric work
C. As soon as the extension brace is discontinued
D. After return to sports practice

Answer Key

QUESTION 1. Correct answer: **B** (see Phase II)

QUESTION 2. Correct answer: **D** (see Phase II)

QUESTION 3. Correct answer: **B** (see Phase IV)

BEYOND BASIC REHABILITATION: RETURN TO SKIING AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

Nicole A. Strick, MPT, and Timothy S. Mologne, MD

Introduction

ASPECTS OF SKIING THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- Knee injuries are some of the most common injuries reported with downhill skiing, with ACL tears accounting for up to 28% of injuries in competitive alpine skiers.[1]
- Safe skiing requires adequate quadriceps strength and endurance, and most ski-related knee injuries occur in the late morning or late afternoon when thigh muscle fatigue is common.
- Safe and effective skiing also requires a stable knee to cut and carve the skis through the snow. Skiing with an unstable knee can predispose one to further injury to the menisci, other ligaments, and to the articular surfaces on the knee.
- Skiing is one of the sports that are associated with ACL tears, even in elite skiers.
- There are three main mechanisms of ACL injuries among professional skiers:
  - A slip-catch, in which the skier is turning and loses balance backward or inward. The outer ski pressure is lost, causing that ski to drift away from the body's center of mass. This knee then extends to regain balance but catches the snowy surface, forcing this straight knee into flexion, internal rotation, and valgus.
  - A dynamic snowplow, in which the skier loses his balance backward with most weight to one ski. The unweighted ski then drifts away from the body, creating a split position while the loaded ski rolls from the outside to the inner edge, catching the snow and forcing an internal rotation of the knee and/or a valgus force.
  - Landing from a jump with backward balance. In this situation, the skier will assume a deeply flexed knee position and may use a strong quadriceps contraction to recover. In the deeply flexed position, hamstring cocontraction is limited during the strong quadriceps pull, which can rupture the ACL. Also, as the skis accelerate forward in relation to the upper body, the stiff ski boot pulls the tibia forward, creating an anterior drawer strain on the ACL[2,3]
- In recreational skiers, an injury coined phantom foot syndrome may occur when a skier falls backward with an increasing load on the inner edge of the ski. The ski then turns uphill, creating a rotational hyperflexion injury.[2,3]

- Following an ACL reconstruction, patients require prolonged rehabilitation to regain adequate motion, strength, and proprioception.
- ACL tendon grafts undergo a ligamentization process, with the graft tissue changing mechanically and biologically for over a year following surgery.
- Clancy et al.[4] has shown that an ACL graft has degradation in strength during this process, with the graft ultimately achieving about 80% of its initial strength at one year following implantation.
- Competitive alpine skiing and racing includes downhill racing, slalom racing, and freestyle mogul and aerial skiing. The forces on the knee during these various skiing styles differ, and each can lead to forces that exceed the tensile strength of the ACL and/or ACL graft.
- As ACL injuries are common, and ACL graft ruptures are reported as high as 22% with competitive alpine skiers[5], patients need to understand and accept the increased risk of reinjury associated with an early return to skiing, particularly freestyle skiing.
- A study of gender differences among competitive alpine ski racers found the rate of re-injury to an ACL graft to be 27% in females and 13% in males.[5]

Literature

- There are no strict medical guidelines with regard to when a patient may return to sports after knee surgery. However, it is generally accepted that one should not begin any sport that places the operative knee at risk until that individual has regained at least 85% of the strength of their unaffected knee, has a stable knee, and does not experience pain or swelling with strenuous activities.[6]
- Extrapolating from Clancy's work[4], ACL grafts achieve about 80% of their initial strength at one year out from implantation.
- Adequate knee strength, proprioception, and patient confidence, along with adequate graft strength and revascularization/incorporation usually occur within 6 to 9 months after ACL reconstruction.
- Returning to skiing for advanced skiers can probably occur sooner than 6 months from surgery, as long as these skiers return to gentle runs on groomed slopes, avoid moguls and other more extreme conditions or techniques, and ski with shorter skis.

Phase I: Advanced Strength and Conditioning Programs

- The principles of progression, overload, and variation should be used to advance training throughout the rehabilitation phases.
- Begin with 3 sets of 10 repetitions for the best strength and power gains, increasing resistance to produce fatigue by the last several repetitions. Progress to 3 sets of 6 to 8 repetitions for advanced weight training when muscular hypertrophy is desired.
- Olympic lifts are recommended for elite athletes and not necessarily recreational competitors unless properly coached.

Phase II: Performance Enhancement Training Techniques

- Training with optimum posture is of the utmost importance. While skiing on a slope, posture should be with slight knee flexion, a neutral spine with forward bent posture at hips, and weight centered above the skis. Arms should be relaxed slightly in front of the body. The forward bent posture increases hamstring activity, a synergist of the ACL, and decreases the knee extension moment and quadriceps activity.[7] Neuromuscular training throughout an athlete's rehabilitation process must stress proper posture with strengthening, balance, plyometric jumping, functional training, sport-specific training, and speed and agility drills for proper muscle memory.
- The principles of progression, overload, variation, individualization, and specificity are all used.
- Repetitions, sets, rest intervals, intensity, training frequency, duration, and volume are based on the specific demand of the downhill event to which the athlete will return.

Phase III: Sport-Specific Training

Program Design/Performance Training Program

Flexibility/Joint Mobility for Joint Stability

- Dynamic warmup prior to activity may include lunge walk with trunk rotation, heel/toe walk, shuffles, cradle walk, backpedalling, skipping, inch worm, high knees, buttock kicks, and straight leg kick with opposite arm touch. Each dynamic exercise is performed for 15 yards. These should be done prior to a workout.
- Good flexibility of hamstrings, quadriceps, gastrocnemius, soleus, hip adductors, ITB, hip flexors and lower and upper trunk rotators is needed to respond to challenging terrain. Static stretches are done after the activity, 3 times for 30 seconds.

Sensorimotor and Balance Training

- Hold each balance challenge for at least 30 seconds times 3. Progress to the next level of difficulty once balance is no longer challenged. Perform daily.
- Move from a narrow base of support to single-leg stance
- Progress from level ground to uneven surfaces (mini trampoline, foam, BOSU, disc, wobble, and balance boards)
- Progress eyes open to eyes closed and use dynamic head, trunk, or upper extremity movement (PNF patterns, body blade movements)

Core Training

Many activities exist, but a few examples are listed below.

- Prone planks (progress from most to least stable: on forearms and knees to being on straight arms and tip toes; from static to dynamic: holding in place versus walking each arm or leg out, then back in or lifting the leg and arm while keeping chest and hips square to the floor). May begin holding for 20 seconds and work to 3 sets of 30 to 60 seconds.
- Side-lying planks (progress from most to least stable: on forearm and knees to being on straight arms/forearm and toes; from static to dynamic: holding in place versus performing a leg lift with the top leg). May begin holding for 20 seconds and work to 3 sets of 30 to 60 seconds. (Figure 32-15)
- Superman (back extension holds) on the ground or using an exercise ball to perform back extensions. May begin holding for 20 seconds and work to 3 sets of 30 to 60 seconds.
- Bicycle crunches (opposite shoulder to knee crunch leading with shoulder, not elbow). Work up to 3 sets of 30 seconds.

Cardiorespiratory/Functional Training

- Running, stationary biking, rollerblading, jump roping, elliptical machine (low resistance), stair machine (low resistance, low stroke), ski machines (begin with short stride, level, low resistance and progress); should use interval training to replicate the demands of skiing (periods of moderate to high level intensity followed by periods of lower intensity) for a duration of at least 20 to 30 minutes, 3 times per week.
- A short duration, straight jogging program may begin when the physician allows, usually around 13 to 16 weeks.

FIGURE 32-15. Side-lying plank with leg lift.

- Physician criteria and timeline vary on return to running. The Cincinnati Sports Medicine Accelerated ACL Rehabilitation Protocol allows ¼ mile straight jogging at weeks 9 to 12 with painless ROM 0° to 135°, at least 4/5 knee and hip manual muscle test, no effusion, no greater than 30% difference from involved to contralateral limb with isometric testing, mean average torque and quadriceps, and hamstrings deficits. There should be joint arthrometer testing of 3 mm or less, good patellar mobility and minimal to no knee crepitus. Progression of running weeks 13 through 26 depends on further criteria of isokinetic testing with goal of no greater than a 20% to 25% difference in torque at 300° per second, and in the percent difference of quadriceps and hamstrings, all tested monthly. At this time, the straight running program distance may be increased to a mile with progression of speed to full by week 26. Further progression at weeks 27 to 52 is based on additional criteria of no greater than 10% to 15% difference in torque at 180° per second and 300° per second, percent difference of quadriceps and hamstrings and isometric testing if a symptomatic patellofemoral joint exists. Functional tests, such as the one-legged distance hop or one-legged timed hop, must be at least 75% of the uninvolved leg at weeks 13 to 26, and 85% at weeks 27 to 52.[8]

Multiplanar Training Activities

- Recommend performing at least 3 days per week.
- Single leg stance star drill (Figure 32-16) (3 sets of 5 repetitions each leg)
- Figure eight runs and, circle runs with affected leg outside and inside (3 sets of 10 repetitions)
- Lateral/diagonal lunges with a medicine ball; onto a BOSU, disc, fitter (3 sets of 10 repetitions)

FIGURE 32-16. Star drill: single-leg stance, maintaining stance knee control while tapping heel or toe to the points of a star with athlete at the center of the star.

- Ski jumps: double or single leg side to side or diagonal jumps (begin 10 seconds times 3 and work up to 3 sets of 30 seconds)
- Diagonal sport cord lunges (3 sets of 10 repetitions), runs (3 times to fatigue)

Training for Optimum Muscle Functional Strength and Power

- Recommend 3 sets of 10 repetitions for the best strength and power gains, increasing resistance to produce fatigue by the last several repetitions. Strengthening

TIMELINE 32-3: **Return to Skiing After ACL Reconstruction**

Weeks 13 to 26 (3 to 6 months)

- Flexibility: hamstring, gastroc-soleus, quadriceps, ITB stretches
- Strengthening: PREs with patellofemoral precautions (3x10)
- Quadriceps: CKC (progress from double to single leg), OKC (90° to 30°)
- Hamstrings/gluteus maximus: machine curls, ball curls, dead lifts
- Hip abductors/adductors: band walks, clams, standing band kicks
- Gastroc-soleus: bent/straight knee raises (progressing double to single)
- Core: prone/side planks with UE/LE raises, superman, bicycle crunches
- Upper body: lat pulldowns, rows, pushups, biceps/triceps, PNF diagonals, rotator cuff
- Balance/neuromuscular Retraining: double to single leg, stable to unstable surfaces, multiplanar, perturbations
- Cardiorespiratory: stationary biking, elliptical, stair or ski machine, walking, swimming
- Running (straight) once criteria are met, usually for 3 to 4 months
- Jogging: 1/4 to 1 mile, progressing speed
- Walking
- Backward running
- Cutting drills: lateral, carioca, figure 8's
- Plyometrics: progress double legged to single, line and box jumps, multiplanar, stable surfaces
- Sport-specific drills: slide board, weighted downhill walks
- PT modalities, cryotherapy as needed

Weeks 26 to 52 (6 to 12 months)

- Flexibility : hamstring, gastroc-soleus, quadriceps, ITB stretches
- Dynamic stretching before activities, static stretching after activities
- Strengthening: PREs with patellofemoral precautions
- Progress to 3 sets of 6 to 8 repetitions for weight training
- Quadriceps, hamstrings/gluteus maximus, hip abductors/adductors, gastroc-soleus, core, upper body
- Balance/neuromuscular: dynamic single leg jumps onto unstable surfaces, multiplanar, with perturbations, UE strengthening
- Cardiorespiratory: progress duration of stationary biking, elliptical, stair or ski machine, walking, swimming
- Running (straight)
- Begin interval training, sprinting
- Backward running
- Plyometrics :progress to multiplanar, multiple jumps onto and over boxes, landing on unstable surfaces in double or single stance
- Speed, agility, and quickness drills: agility ladder, cone and dot drills, speed circuits
- Sport-specific drills progressed
- PT modalities, cryotherapy as needed

FIGURE 32-17. Dynamic knee curl in bridged position. Hips should remain level throughout.

days should be alternated with plyometric and agility days. With further training on weight machines, PREs may be increased to 3 sets of 6 to 8 repetitions and eventually progressed to 1-repetition maximum training.

- Hamstrings/gluteus maximus: hamstring curl machine, supine bilateral knee curl on exercise ball (Figure 32-17), dead lift with row, bridging with leg lift
- Quadriceps: single leg squats (Figure 32-18),[9] wall sits and single leg wall squats with ball, knee extension machine (30° to 90°), single and double-legged leg press, plyometric leg presses, lunges (back leg on exercise ball, dumbbells in hands) (Figure 32-19)
- Hip abductors/adductors: Thera-band hip abductor walks keeping hips level (Figure 32-20), side-lying hip abduction, standing hip abduction and adduction with Thera-Band, side-lying clam with band around knees
- Gastrocnemius and soleus: bent and straight knee heel raises (double or single leg) with resistance

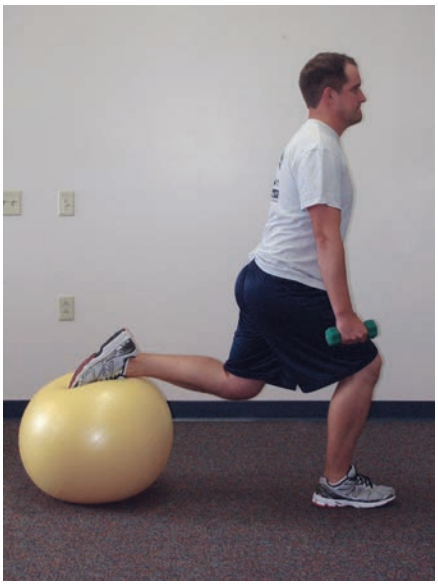

FIGURE 32-19. Lunges with back leg on exercise ball with dumbbells. Ensure proper knee control with no valgus moments. Toes point straight ahead. Front knee does not go beyond toes.

- Upper extremities: lat pulldowns, bilateral upper extremity PNF diagonals, dumbbell rows, pushups, biceps curls, and triceps extension for strength in pushing off of ski poles

Neuromuscular Dynamic Stability Exercises

- Recommend 3 sets of 10 repetitions working up to 3 sets of 30 seconds, at least 5 days per week. Proper form is crucial throughout these activities. This includes maintaining level hips, good trunk control, avoiding genu valgum moments, and avoiding placement of knees beyond toes.

FIGURE 32-18. Single-leg squat. Do not allow knee valgus, a dropped pelvis, or knees to go past toes.

FIGURE 32-20. Thera-Band hip abductor walk. Maintain squatted position, feet and knees pointed forward.

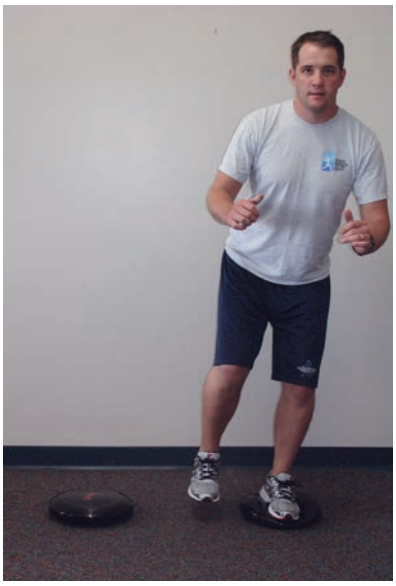

FIGURE 32-21. Single-legged jump side to side onto disc. Maintain proper LE alignment and good trunk control.

- Using a wobble board or BOSU in single-leg activities (catching a ball, using a body blade, performing PNF patterns, UE strengthening)
- Single leg lateral jumps onto a BOSU or disc (Figure 32-21)
- Forward or side lunges using a fitter
- Single-leg line jumps (forward/retro, side/side, diagonally)

Training for Speed, Agility, and Quickness

- Agility ladder drills: may begin with fast feet forward, retro, lateral; 180° slalom jump turns, forward and backward slalom jumps (Figure 32-22) and may be progressed further for mental and coordination challenges. Perform 2 to 3 agility ladder sessions per week, allowing at least 48 hours between. Select 4 to 6 drills and 3 to 5 sets of each per workout.
- Dot drills: double or single leg; work up to 3 sets of 20 to 30 seconds with 30 seconds rest between.
- Cone drills: T, clover, star, W drills (adding change in direction with cutting, sprinting, backpedaling, shuffling). Perform 4 to 6 sets in each direction with 1-minute rest between.
- Speed circuits (components of sprinting with cutting, jumping over hurdles, shuffling) Perform 4 sets in each direction with 1 to 2 minutes of rest between.

Plyometric Training

- Correct posture is extremely important for knee safety with jumping. A defensive or athletic posture is used. Shoulders should be gently retracted with an erect spine, chest over knees, and knees not going past the toes.
- Landings should be soft and quiet with knees bent and toe to heel rocking, avoiding knee valgus or varus moments. (see Figure 32-22 for posture) Jump may progress from 15 to 30 seconds and from 2 to 3 sets with 30 second rest times between jumps. Recommend performing 2 to 3 times per week with at least 24 hours between.
- Training should be performed while the athlete is fresh and should be stopped when fatigue limits proper technique.[10]
- Squat, tuck, lunge, broad, and 180° jumps, squat jump from floor to box, bounding for distance and height
- Line, cone, and hurdle jumps: increase height, perform multidirectional patterns, double to single leg
- Multiple single-leg jumps; double-leg to single-leg jumps, sticking the landings on soft, controlled knees (5 to 10 times per leg)
- Forward and lateral jumps onto and over plyo boxes with focus on soft, controlled landings, gradually increasing box height, 5 to 10 times each.

Sport-Specific Training

- Recommend 5 times per week, changing drills daily.
- Cutting and pivoting drills simulating turns: Distances and angles similar to specific downhill events or diagonal cutting 5 to 10 feet apart for 20 to 40 feet. The number of repetitions is dependent on the distance and fatigue. Consider 3 to 5 repetitions.
- Walking downhill with a weighted vest or back pack to simulate eccentric quadriceps loading: Repetitions dependent on hill slope and distance; consider 2 to 6 repetitions.
- Box jumps onto a BOSU or disc in double or single leg, sticking the landing (Figure 32-23): Perform 3 sets of 5 to 10 repetitions on each leg.
- Lateral single leg jumps onto a BOSU or disc (Figure 32-21): Perform 3 sets of 5 to 10 repetitions on each leg.
- Slide board conditioning (Figure 32-24): Work up to performing this for the time duration of a downhill run.

FIGURE 32-22. Proper skiing defensive position posture. Bilateral-legged slalom jump can be performed by starting to the right of the first square, then jumping across the ladder to the left of the second square. Repeat this sequence until the end of the ladder. May progress to single-legged jump.

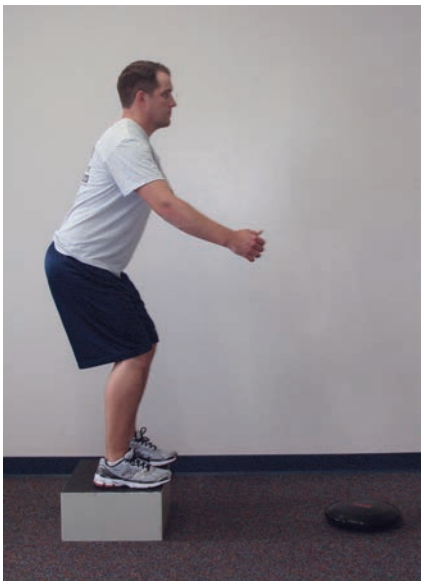

FIGURE 32-23. Bilateral leg to single-leg box jump onto a disc.

Application of Acute Training Variables

- The principles of progression, overload, and variation should be used to advance training. Every program should be individualized to the unique demands of the specific skiing style of the individual, whether vertical or forward explosion is needed or quick cutting movement. Exercises and repetitions should be varied throughout for continual strength gains.
- In general, one may begin with 3 sets of 10 to 20 repetitions for endurance, progressing to 3 sets of 6 to 8 repetitions for weight training, and eventually 1-repetition maximum training.
- Intensity of aerobic conditioning should be matched to the demands of the particular skiing style. For skiing, this is usually periods of moderate to high-level intensity followed by periods of rest to lower intensity.
- Both strengthening and conditioning should occur 3 days per week on alternating days for a total of 6 days per week.

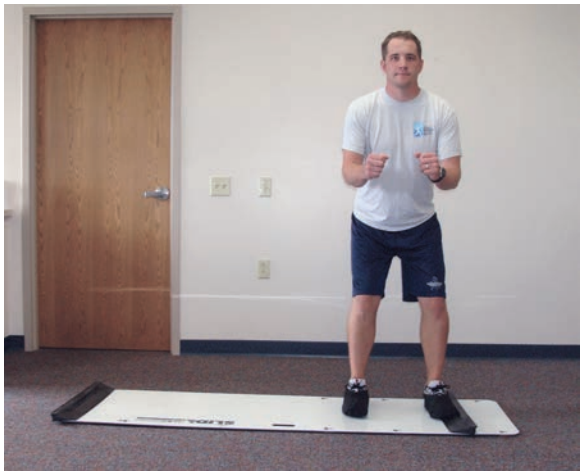

FIGURE 32-24. Slide board conditioning.

- Conditioning should last at least 20 to 30 minutes. Plyometrics should be done 3 times per week.

Sports Performance Testing

General Information

- General history
- Medical history, including medical ailments, genetic conditions that might affect strength, ligamentous laxity, and proprioception
- Sports injury history, including the specifics of the current knee injury and prior knee injuries
- Surgical history, including specifics on the ACL reconstruction (graft type, concomitant pathology to collateral ligaments, menisci, and articular surfaces, as well as specific treatment for these concomitant injuries; occurrence of any postoperative complications, including motion loss, infection, neurologic injury, or thromboembolic events.

Objective Tests

- Single-leg hop for distance and one-legged hop time: During weeks 13 to 26, affected leg should be at least 75% of unaffected; during weeks 27 to 52, affected leg should be at least 85% of unaffected to return to sport.[6,8]
- Drop jump test: Video record and visually analyze an athlete jumping from a 12-inch box. Require proper landing techniques of flexed knees, level hips, a soft landing on the ball of the foot, and an absence of a valgus moment at the knees. An athlete should meet these requirements before plyometric progression. Video analysis can be qualitatively performed frame by frame by a physical therapist trained in proper biomechanics. More quantitative measurements can be made if a biomechanics lab and equipment for joint marking is available. The goal is greater than 60% normalized knee separation distance. This measures combined hip, knee, and ankle mechanics.
- Physiological assessments: At this stage, knee AROM should be at least 0° to 135° and nearing equal to the uninvolved knee if this is more. Hip, ankle, and knee MMT should be a full 5 of 5.
- Static/dynamic postural assessments of gait, running, and jump training are made visually, with a recording or with the use of a biomechanics lab.

Sport-Specific Testing

- Ability to perform any sport-specific exercises with proper core and lower extremity muscular control. The functional testing algorithm presented by Davies and Zillmer should be completed by the athlete at the end of this phase if they plan to return to sport.[12]
  - Subjective: pain <3 on VAS
  - Basic measurements: <10% bilateral comparison
  - KT 1000 ligamentous test: <3 mm bilateral comparison
  - Balance test: <30% bilateral comparison

- CKC supine isokinetic test: <30% bilateral comparison
- OKC isokinetic test: <25% bilateral comparison
- CKC squat isokinetic test: <20% bilateral comparison
- Functional jump test: <20% bilateral comparison
- Functional hop test: <15% bilateral comparison
- Lower extremity functional test (LEFT): <90 seconds for males; <120 seconds for females
- Sport-specific test: <10% bilateral comparison

Specific Criteria to Determine Readiness for Skiing

- To enter Phase III, an athlete should have a normalized gait pattern with full nonpainful knee active range of motion (0° to 135°) and no swelling.
- To return to skiing, an athlete should complete the functional testing algorithm presented by Davies and Zillmer.[12]

Specific Criteria for Releasing an Athlete to Unsupervised Complete Participation in Skiing

- Unfortunately, a systematic review involving 21 clinical outcome studies for return to athletics, after ACL reconstruction from April 2001 to April 2011, found that few objective functional criteria have been published. The most common criterion was lower extremity muscle strength, followed by lower limb symmetry testing and knee examination parameters of range of motion and effusion.[11] Many authors advocate for a functional testing program versus a time based return to sport, however.
- It is generally accepted that one should not begin any sport that places the operative knee at risk until that individual has regained at least 85% of the strength of their unaffected knee. This is assessed functionally with a single-leg hop for distance or one-legged hop time test or more objectively with dynamometer, isokinetic, or isotonic 1-repetition maximum testing of quadriceps and hamstrings.
- Other return to sport variables as recommended by the Sportsmetrics ACL return to play checklist may include:
  - Jump analysis (previously described)
  - Single-leg squat test: Athlete stands on a box with hands on hips and performs 5 squats on each leg. Athlete is rated on position of hip and knee joints. Measures core, hip, and knee muscle strength. Goal is subjective rating of good; no knee valgus or pelvic tilt.
  - Vertical jump: The highest point the athlete can reach while jumping straight up minus the highest point they can reach while standing flat-footed. Measures explosive power and muscle strength. Goal is ≥ 14 inches
  - Core strength: Number of full sit-ups (knees to elbows) an athlete can perform in 1 minute. Measures abdominal/core strength. Goal is ≥ 70th percentile: 38 or more curl-ups per minute
  - Cutting drill: Athlete performs a 45° cut. Ability to keep erect posture, stable trunk (no rotation or lean), increased knee and hip flexion, maintain upper body over knees
- Again, the functional testing algorithm presented by Davies and Zillmer is recommended before an athlete returns to sport.[12]

Recommended Ongoing Exercises

- An athlete must continue with a program to maintain proper conditioning, flexibility, core strength, and balanced lower extremity strength, especially quadriceps and hamstrings, to participate safely in skiing.

Evidence

Barber-Westin S, Noyes F: Objective criteria for return to athletics after anterior cruciate ligament reconstruction and subsequent re-injury rates: A systematic review. *Phys Sports Med* 39:100–110, 2011.

This systematic review assessed the objective functional criteria used to determine when patients can return to athletics postoperatively and to determine the rates of reinjury to ACL reconstructed knees. (Level IV evidence)

Bere T, Florenes TW, Krosshaug T, et al: Mechanisms of anterior cruciate ligament injury in World Cup alpine skiing. *Am J Sports Med* 39:1421–1429, 2011.

This case series of 20 anterior cruciate ligament injuries reported through the International Ski Federation Injury Surveillance System for the 2006 to 2009 World Cup seasons was obtained on video. Seven international experts in skiing biomechanics and sport medicine performed visual analyses of each case, describing injury mechanisms in detail and created 3 main categories of injury in the elite skier: slip-catch, landing back-weighted, and dynamic snowplow. (Level IV evidence)

Beutler AI, Cooper LW, Kirkendall DT, et al: Electromyographic analysis of single-leg, closed chain exercises: Implications for rehabilitation after anterior cruciate ligament reconstruction. *J Athl Train* 37:13–18, 2002.

This prospective study of 18 normal subjects measured the knee angle and surface EMG activity from thigh muscles while performing unsupported one-legged squats and step-ups. Their findings indicate that one-legged squats and step-ups would be effective in muscle rehabilitation and may be protective of the ACL graft as functional, closed chain activities. (Level IV evidence)

Clancy WG, Narechania RG, Rosenberg TD, et al: Anterior and posterior cruciate ligament reconstruction in Rhesus monkeys. *J Bone Joint Surg Am* 63:1270–1284, 1981.

This study of 29 young adult Rhesus monkeys used microangiographic, histological, and biomechanical techniques to study the vascularity and tensile strength of the medial third of the patellar tendon after being implanted as a graft for the ACL or PCL. Grafts were found to revascularize at week 8.

At one year, they had approximately 80% of the tensile strength prior to the transfer. (Level IV evidence)

Davies G, Zillmer D: Functional progression of exercise during rehabilitation. In Ellenbecker TS, editor: *Knee Ligament Rehabilitation*, London, 2000, Churchill Livingstone, pp 345–360.

The functional testing algorithm presented in this article serves as a guideline for clinicians to determine when an athlete is ready to return to sport after injury. (Level IV evidence)

Heckmann T, Noyes FR, Barber-Westin SD: Rehabilitation of primary and revision anterior cruciate ligament reconstructions. In Noyes FR, Barber-Westin SD, editors: *Noyes' Knee Disorders: Surgery, Rehabilitation, Clinical Outcomes*, Philadelphia, 2009, Saunders, pp 306–336.

This rehabilitation protocol for primary ACL reconstruction with early return to strenuous activities describes weeks 6 through 52 after ACL reconstruction using a central one-third bone patellar tendon bone graft, isometrically placed. This protocol was not recommended for low strength grafts, nonisometric grafts, or grafts not securely fixed. The protocol is supported primarily by clinical success rates. (Level V evidence)

Hewett TE, Stroupe AL, Nance TA, et al: Plyometric training in female athletes: Decreased impact forces and increased hamstring torques. *Am J Sports Med* 24:765–773, 1996.

This prospective study of 11 female high school volleyball players tested the effect of a jump training program on landing mechanics and lower extremity strength. The program goal was to decrease landing forces after proper training with neuromuscular control exercises; 10 of 11 female subjects decreased peak landing forces. (Level IV evidence)

Johnson SC: Anterior cruciate ligament injury in elite alpine competitors. *Med Sci Sports Exerc* 27:323–327, 1995.

This article discussed modern ski bindings and their effect on ACL injuries as well as the mechanism of ACL injury in the recreational and elite skier. (Level V evidence)

Koyanagi M, Shino K, Yoshimoto Y, et al: Effects of changes in skiing posture on kinetics of the knee joint. *Knee Surg Sports Traumatol Arthrosc* 14:88–93, 2006.

This prospective study of 10 females with no past history of leg injury compared forward versus backward bent postures. It found that a forward bent posture with the knee slightly bent was the safest form of skiing for prevention of ACL injury. (Level IV evidence)

Noyes FR, Barber SD, Mangine RE: Abnormal lower limb symmetry determined by function hop tests after anterior cruciate ligament rupture. *Am J Sports Med* 19:513–518, 1991.

This prospective, randomized study of 67 patients compared the sensitivity of four different types of one-legged hop tests to determine alteration in lower limb function in ACL deficient knees. It found a low sensitivity, high specificity, and low false positive rate, allowing the tests to be used only to confirm suspected lower limb functioning deficits. A limb symmetry index of 85% or greater was found to be within the normal range for both males and females, regardless of dominance, sports activity level, or gender. (Level IV evidence)

Pujol N, Blanchi MPR, Chambat P: The incidence of anterior cruciate ligament injuries among competitive alpine skiers: A 25-year investigation. *Am J Sports Med* 35:1070–1074, 2007.

This descriptive study of 379 elite French national ski team members evaluated epidemiologic aspects of ACL injuries from 1980 to 2005. They found overall ACL incidence rates and reinjury rates to the same knee as well as the rate of ACL injury to the contralateral knee. (Level IV evidence)

Stevenson H, Webster J, Johnson R, et al: Gender differences in knee injury epidemiology among competitive alpine ski racers. *Iowa Orthop J* 18:64–66, 1998.

This retrospective study included 404 returned questionnaires from Vermont Alpine Racing Association Members and several New England NCAA Division I ski racing programs. The survey included questions regarding the racer's age, gender, number of skiing years, injury and surgery to knees, and reinjury to an ACL repaired knee. It found that 36% of those having ACL reconstructions required subsequent surgery to the same knee. (Level IV evidence)

Multiple-Choice Questions

QUESTION 1. With plyometric jumping, which of the following is not true?

A. Landings should be soft so that muscles absorb the shock from the knee joint.
B. Landings should be with heel to toe contact.
C. Landings should be without knee valgum or varus moments.
D. Landings should be with knees flexed.

QUESTION 2. What percent of the unaffected leg should an athlete attain on the single-leg hop test before returning to sport?

A. 60%
B. 75%
C. 85%
D. 95%

QUESTION 3. At one-year postoperative ACL reconstruction, what percent strength is the graft compared to its original tensile strength?

A. 30%
B. 50%
C. 80%
D. 100%

QUESTION 4. Which mechanism of injury is not included in current research describing ACL rupture in the elite skier?

A. Landing toe-weighted
B. Slip-catch
C. Landing back-weighted
D. Dynamic snowplow

Answer Key

QUESTION 1. Correct answer: **B** (see the Plyometric Training of Phase III: Sport-Specific Training)

QUESTION 2. Correct answer: **C** (see Objective Testing)

QUESTION 3. Correct answer: **C** (see Clancy et al.[4])

QUESTION 4. Correct answer: **A** (see Bere et al.[2])

POSTOPERATIVE REHABILITATION AFTER SOFT TISSUE ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION (AUTOGRAFT AND ALLOGRAFT)

Sanjeev Bhatia, MD, Geoffrey S. Van Thiel, MD, MBA, John Bojchuk, ATC, and Bernard R. Bach, Jr., MD

Indications for Surgical Treatment

The decision to go forward with an ACL reconstruction procedure is dependent on various factors and is highly individualized to each patient. Nonetheless, ACL reconstruction is generally recommended in the following circumstances:

- Young, highly demanding patients
- Those with a desire to return to competitive or frequent recreational sports requiring cutting or pivoting
- Patients with combined ligament knee injuries, significant instability, or repairable meniscus tears

Brief Summary of Surgical Treatment

Major Surgical Steps

- General anesthesia with the patient in the supine position
- Physical exam or diagnostic arthroscopy to document all pathology
- Soft tissue graft harvest and/or preparation
- Preparation of notch and takedown of leftover ACL stump
- Tibial tunnel creation
- Femoral tunnel creation
- Graft passage through tibial and femoral tunnels
- Fixation of the ACL graft in femoral tunnel
- Fixation of ACL graft in tibial tunnel
- Wound closure

Factors That May Affect Rehabilitation

Anesthetic

- Regional anesthesia, frequently in the form of a femoral nerve block, may provide excellent postoperative analgesia, leading to improved outcomes. However, the block may wear off 8 to 24 hours after surgery. Be cognizant of rebound pain, and be quick to use other modalities.

Surgical

- Presence of other knee pathology
  - Frequently, patients undergoing ACL reconstruction are noted to have other knee pathology preoperatively or at the time of diagnostic arthroscopy. These may include other ligamentous injuries, meniscus tears, or cartilage injuries. It is important to determine whether any other injuries exist or concomitant procedures were performed, as this may change postsurgical rehabilitation.

- Autograft versus allograft ligament reconstruction
  - ACL grafts may be derived from the patient's own tissue (autografts) or cadaveric tissue (allografts). The autograft soft tissue most commonly used for ACL reconstruction is the hamstring tendons (semitendinosus and gracilis tendons, frequently a quadrupled stranded construct). However, it is becoming more common to also use an autograft quadriceps tendon. Allograft options for soft tissue ACL reconstruction include hamstring tendons, tibialis anterior tendon, and Achilles tendon grafts. It is important to know whether any autograft tendon was harvested in your patient as this may influence hamstring postsurgical rehabilitation.
- Graft type and graft fixation
  - ACL reconstruction can be performed with a soft-tissue graft (hamstring, Achilles tendon, tibialis anterior, quadriceps) or a bone-tendon-bone graft (patellar tendon with two bone plugs).
  - Accelerated rehabilitation programs, similar to those commonly used following ACL reconstructions using the patellar tendon autograft, have been shown to be equally successful following reconstruction with a hamstring graft.
  - In cases where tibial or femoral tunnel fixation of the grafts are not as strong, a slightly less aggressive rehabilitation protocol may be suggested.
  - Soft tissue-to-bone healing takes 12 weeks to complete in most instances whereas bone-to-bone healing occurs in approximately 8 weeks.

Before Surgery: Overview of Goals, Milestones, and Guidelines[1]

A patient with an ACL tear can commonly present with a swollen, stiff, and painful knee. The hemarthrosis after the injury can produce an inflammatory reaction that causes significant discomfort/dysfunction. The goals of preoperative rehabilitation are to decrease swelling, return knee motion to normal or near normal, improve strength, and begin early therapy training. Achieving normal knee range of motion has been shown to decrease the probability of postreconstruction stiffness. To achieve preoperative goals:

Tools to Manage Swelling

- Cryo/compression devices: there are multiple commercially available devices that provide cooling and/or compression to the knee. These devices can also be used in the postoperative time period.

Restoration of Normal Knee Range of Motion

- Exercise training preoperatively that can also be used postoperatively.

[1]*Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

FIGURE 32-25. Towel stretch exercise. The towel is used to lift the heel of the affected leg to end range knee hyperextension by pulling the towel upwards.

- Towel stretches: a looped towel around the midfoot is held with one hand as the foot is lifted and the other hand holds the thigh down (Figure 32-25).
  - An advancement of this is to have the patient contract the quadriceps and release the towel to hold the heel off the bed/ground.
- The affected leg should also be allowed to rest on a pillow with nothing under the knee. This encourages full extension.
- Wall and heel slides can be implemented to assist with flexion. The patient can be laying supine with the affected leg/foot extended against a wall. The foot is then allowed to slide down into flexion with assistance from the other leg as necessary.
- Quad sets and straight leg raises
- Full weight bearing and ROM is encouraged.
- Activity can be completed as tolerated and good exercises include the stationary bike and elliptical machine.

GUIDING PRINCIPLES OF POSTOPERATIVE REHABILITATION

- Obtaining full passive knee extension and patellar mobility immediately following surgery
- Reducing postoperative inflammation and pain with the use of various modalities
- Restoring neuromuscular control with electrical muscle stimulation (for reestablishing voluntary quadriceps control), proprioceptive training, and other biofeedback modalities
- Gradually increasing applied loads to the knee
- Progressing to sport-specific training

Phase I: Immediate Postoperative Period (days 0 to 14)

Clinical Pearls

One of the most frequently seen complications following ACL reconstruction is the loss of full knee extension, thus creating an environment ripe for scar

tissue formation. Lack of extension also often leads to increased patellofemoral and tibiofemoral joint contact pressure, difficulty with quadriceps activation, and excessive muscular fatigue. A drop-lock knee brace locked at full extension is often helpful, particularly when patients use it while ambulating and sleeping at night for 2 to 3 weeks after surgery.

Goals

- Restoring full or near normal passive knee extension
- Reducing joint swelling and pain
- Restoring patellar mobility
- Progressively improving knee flexion
- Reestablishing voluntary quadriceps control
- Restoring independent ambulation

Protection

- A drop-lock knee extension brace locked in full-extension is used immediately postoperatively
- The brace is worn in extension for 6 weeks during ambulation and sleeping activities if an autograft tendon was used, and 10 to 14 days if an allograft tendon was used.
- Crutches may be used for comfort initially but patients should try to assume full weightbearing by the second week. To facilitate the transition from crutches to full weightbearing, one may allow 2 crutches for the first 7 to 10 days, then progress to 1 crutch and finally full weightbearing by 14 days.
- Weightbearing may be altered if the patient has other concomitant injuries (bone bruise) or other concomitant procedures are performed

Management of Pain and Swelling

Management of Pain/Analgesia

- In addition to oral analgesic medication, cryotherapy devices can be helpful. These units consist of a cooling apparatus and wrap that helps to decrease pain and spasm. It is thought that cryotherapy works by inhibiting afferent nerve conduction and decreases the local inflammatory response.
- Passive range of motion may support the neuromodulation of knee pain following surgery and improve symptoms.

Management of Swelling

- It is imperative to reduce knee swelling whenever possible in the immediate postoperative period.
- Knee effusions may cause muscle inhibition.
- Cryotherapy and joint compression with a knee sleeve, ace wrap, or compression device are the most frequently used modalities.
- The patient can also ice 20 minutes hourly and elevate lower extremity.

Techniques for Progressive Increase in Range of Motion

- Full passive knee extension (days 1 to 7)
- Achieve 90° of knee flexion (days 2 to 7)
- Patellar mobilization

Other Therapeutic Exercises

- Ankle pumps
- Heel slides/wall slides
- Prone leg hangs for extension
- Hamstring stretches (Do not do until 4 weeks postoperatively if hamstring autograft used in surgery)
- Straight leg raises (hip flexion, abduction, adduction)
- Aerobic conditioning
  - Upper extremity ergometry
  - Well-leg bicycling

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Quadriceps isometric (days 1 to 14)
- Standing hamstring curls (Do not do until 6 weeks postoperatively if hamstring autograft used in surgery)
- Straight leg raise in all planes with the brace until the quadriceps are strong enough to prevent an extensor lag.
- Electrical stimulation of quads (4 to 6 hours daily)

Sensorimotor Exercises

- Active/passive joint positioning
- Balancing activities
- Stable platform, eyes open
- Stable platform, eyes closed
- Seated ball throwing and catching

Open and Closed Kinetic Chain Exercises

- Mini-squats
- Weight shifts

Milestones for Progression to the Next Phase

- Ability to achieve full passive knee extension
- Passive knee flexion from 0° to 90°
- Minimal knee swelling
- Good patellar mobility
- Quad strength and control as demonstrated by ability to perform good quad set and straight leg raise with no extensor lag
- Ambulation without crutches

Phase II: Postoperative (weeks 2 to 4)

Clinical Pearls

At this phase, patients should be able to ambulate independently without crutches. The brace should be discontinued around week 2 if an allograft was used but should be continued until week 6 if an autograft tendon was used. As this phase progresses, closed chain exercises gradually become more difficult. Pool work should only be performed if surgical wounds are fully closed.

Goals

- Maintain range of motion (full knee extension) and patellar mobility established in previous phase.
- Gradually increase knee flexion.
- Diminish swelling.
- Muscle training
- Muscle proprioception

Protection

- Full ambulation without crutches or a brace should be achieved by this phase

Management of Pain and Swelling

Management of Pain

- In addition to oral analgesic medication, cryotherapy, electrical stimulation, and transcutaneous electrical neuromuscular stimulation (TENS) devices may be helpful.

Management of Swelling

- Cryotherapy and joint compression with a knee sleeve or ace wrap are the most frequently used modalities.
- The patient can ice for 20 minutes hourly and elevate the lower extremity.

Techniques for Progressive Increase in Range of Motion

- Self-performed range of motion stretching exercises should be performed 4 to 5 times daily. There should be an emphasis on maintaining full, passive range of motion (full extension and full flexion).
- Overpressure into extension
- Passive range of motion from 0° to 115° flexion (by week 3)
- Continue patellar mobility

Other Therapeutic Exercises

- Bicycle
- Straight leg raises (hip flexion, adduction, abduction, extension)
- Pool walking (begin at earliest during week 3, only if incision is fully closed)

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Isometric quadriceps sets
- Leg press (Figure 32-26)
- Knee extension 90° to 40° without weight
- Leg external and internal rotation maneuvers with knee bent 30° to engage popliteus and hamstring muscles
- Calf raises with knee in extension
- Bent knee calf raises for soleus
- Hamstring curls (Do not do until 6 weeks postoperative if hamstring autograft used in surgery)

Sensorimotor Exercises

- Bicycle
- Progress to proprioception drills as tolerated

Open and Closed Kinetic Chain Exercises

- Half squats
- Weight shifts
- Front and side lunges
- Eccentric quadriceps program (isotonic exercises only)
- Lateral step-ups
- Front step-ups
- Stair-stepper machine

TIMELINE 32-4: **Postoperative Rehabilitation After Soft Tissue ACL Reconstruction (Autograft and Allograft)**

PHASE I (weeks 1 to 2)	PHASE II (weeks 2 to 4)	PHASE III (weeks 4 to 10)
• Knee extension brace locked in full extension • Crutches for comfort, WBAT • ROM: full passive knee extension and 90° knee flexion • Patellar mobilization • Ankle pumps, wall slides, SLR, prone leg hangs	• Slowly discontinue brace and crutches • PT modalities • Overpressure into full knee extension • Passive ROM from 0° to 115° flexion • Continue patellar mobility • Bicycle, SLR • Isometric quad sets, half squats • Front and side lunges • Lateral step-ups • Front step-ups • Perturbation training • Bicycling for endurance	• No brace or crutches • PT modalities as needed • PROM-full, continue self-performed ROM exercises • Bicycle • SLR (hip flexion, adduction, abduction, extension) • Pool running (backwards/forward) • Leg press • Hamstring curl (begin at 6 weeks postop if hamstring autograft was harvested) • Progress isometric strength program • Balance training on tilt board and with medicine ball throws • Lunge exercises • Wall squats, vertical squats, toe calf raises • Open chain resistance with extension; begin slowly with 1 lb weight • Stair-stepper machine • Perturbation training

Techniques to Increase Muscle Strength, Power, and Endurance

- Bicycling for endurance

Neuromuscular Dynamic Stability Exercises

- Perturbation training

Milestones for Progression to the Next Phase

- Active range of motion from 0° to 115° knee flexion
- Isometric quadricep strength is at least 60% of the contralateral side
- No joint line or anterior knee pain
- Lack of knee effusion

FIGURE 32-26. Leg press.

Phase III: Postoperative (weeks 4 to 10)

Clinical Pearls

As this phase progresses, difficulty of exercises (particularly those involving neuromuscular control and proprioception) also increases. Plyometrics may be incorporated by week 6.

Goals

- Continue to increase strength
- Continue to increase range of motion (0° to 125°)
- Increase proprioception, balance, and neuromuscular control
- Improve endurance
- Improve limb confidence

Protection

- No more brace or crutches if an allograft was used, continue the brace until week 6 with an autograft.

Management of Pain and Swelling

- Cryotherapy, electrical stimulation, and transcutaneous electrical neuromuscular stimulation (TENS) devices may be helpful.
- Narcotic pain medication should not be used at this point.
- Continue the joint compression with a knee sleeve or ace wrap.
- Ice the knee for 20 minutes hourly and elevate lower extremity.

TIMELINE 32-4: **Postoperative Rehabilitation After Soft Tissue ACL Reconstruction (Autograft and Allograft)** (Continued)

PHASE IV (weeks 10 to 16)	PHASE V (weeks 16 to 22)	Weeks 22 to 52
• PT modalities as needed • PROM-full • Bicycle • Straight leg raises • Progress pool running • Can start running straight ahead at 12 weeks • Leg press, hamstring curls • Progress isometric strengthening programs • Perturbation training on a single leg • Continue balance training with medicine ball • Continue open chain resistance training • Biodex stability system • Initiate plyometric leg press by weeks 12 to 16 • Initiate sport-specific exercises (cone drills, side shuffles, cariocas, cutting) • Combinations of agility drills	• PROM-maintain full motion • Bicycle • Straight leg raises • Continue to progress pool running; full forward and backwards running • Increase cutting maneuvers • Leg press, hamstring curls • Progress isometric strengthening programs • Perturbation training on a single leg • Progress open chain resistance training • Biodex stability system • Progress plyometric leg press and sport-specific plyometric drills • Continue sport-specific exercises (sudden start/stops, cone drills, agility drills) • Sport-specific skill training (e.g., coming out of 3-point stance for football lineman)	• Gradual return to sports participation • Contact athletes should first return to practice on limited basis before full contact • Maintenance program for strength and endurance • Continue sport-specific skill training

Techniques for Progressive Increase in Range of Motion

- Self-performed range of motion stretching exercises should be performed 4 to 5 times daily. There should be an emphasis on maintaining full, passive range of motion (full extension and full flexion).
- Perform hamstring stretching at this stage if a hamstring autograft was used during ACL surgery.

Other Therapeutic Exercises

- Bicycle
- Straight leg raises (hip flexion, adduction, abduction, extension)
- Pool running (provided no wound healing problems); begin with backward running and hip/leg exercises, then progress to forward running

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Leg press
- Hamstring curls (begin at 6 weeks postoperatively if hamstring autograft used during ACL reconstruction)
- Progress isometric strengthening program

Sensorimotor Exercises

- Balance training on a tilt board
- Balance training with medicine ball throws
- Perturbation training

Open and Closed Kinetic Chain Exercises

- Lateral lunge step-overs
- Front and side lunges
- Lateral step-downs
- Front step-downs
- Wall squats
- Vertical squats
- Toe calf raises
- Open chain resistance with extension can begin with 1 lb weight only. Increase no more than 1 lb per week. (Figure 32-27)
- Stair-stepper machine

FIGURE 32-27. Open chain knee extension with leg weight. This exercise should begin with no more than 1 lb of resistance. Each week, increase resistance by 1-lb increments if tolerated.

Techniques to Increase Muscle Strength, Power, and Endurance

- Stair-stepper machine
- Bicycle
- Walking program

Neuromuscular Dynamic Stability Exercises

- Biodex stability system
- Balance training on a tilt board
- Balance training with medicine ball throws
- Perturbation training

Milestones for Progression to the Next Phase

- Active range of motion maintained at 0° to 125° flexion
- Isometric quadricep strength is greater than 80% of the contralateral side
- Knee flexor/extensor strength ratio is at least 70% to 75%
- No pain
- No joint effusion
- Hamstring strength is equal bilaterally
- Hop test (80% that of contralateral leg)

Phase IV: Postoperative (weeks 10 to 16)

Clinical Pearls

> This is the phase that most patients have been waiting for: a gradual return to sport-specific training. The eager athlete must be reminded that a progression is necessary and they need to remain committed to the process and protocol.

Goals

- Return leg strength to normal
- Improve muscular power and endurance
- Enhance neuromuscular control
- Perform sport-specific drills

Protection

- No more brace or crutches for the majority of patients. However, some patients such as football lineman may benefit from the use of a functional ACL brace at this point.

Management of Pain and Swelling

- Pain should be minimal to nonexistent at this point.
- Cryotherapy, electrical stimulation, and transcutaneous electrical neuromuscular stimulation (TENS) devices can be used when necessary.
- Narcotic pain medication should not be necessary at this point.
- Joint compression with a knee sleeve or ace wrap are the most frequently used modalities.
- Ice for 20 minutes hourly and elevate lower extremity.

Techniques for Progressive Increase in Range of Motion

- Self-performed range of motion stretching exercises should be performed 4 to 5 times daily. There should be an emphasis on maintaining full, passive range of motion (full extension and full flexion).

Other Therapeutic Exercises

- Bicycle
- Straight leg raises (hip flexion, adduction, abduction, extension)
- Pool running (provided no wound healing problems); forward and backwards running
- Can start running straight ahead at 12 weeks

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Hamstring curls
- Leg press
- Progress isometric strengthening program

Sensorimotor Exercises

- Continue balance training on a tilt board
- Continue balance training with medicine ball throws (Figure 32-28)
- Continue perturbation training on single leg (Figure 32-29)

Open and Closed Kinetic Chain Exercises

- Lateral lunge step-overs
- Front and side lunges
- Lateral step-downs
- Front step-downs
- Wall squats (Figure 32-30)
- Vertical squats
- Toe calf raises
- Continue open chain resistance with extension; after beginning with 1 lb in week 3, increase no more than 1 lb per week.
- Stair-stepper machine

FIGURE 32-28. Single-leg balance training with medicine ball throws. This medicine ball exercise is performed while balancing on a tilt board with one leg.

FIGURE 32-29. Single-leg perturbation training using a tilt board.

Techniques to Increase Muscle Strength, Power, and Endurance

- Stair-stepper machine
- Bicycle
- Walking program

Neuromuscular Dynamic Stability Exercises

- Biodex stability system
- Balance training on a tilt board
- Balance training with medicine ball throws
- Perturbation training

Plyometrics

- Initiate plyometric leg press by weeks 12–16 (Figure 32-31)

FIGURE 32-30. Wall squats.

FIGURE 32-31. Plyometric jumping exercises.

Functional Exercises

- Lunges with sport cord
- Running and agility progression
- Pool running (backward and forward)

Sport-Specific Exercises

- Cone drills
- Side shuffles
- Cariocas
- Sudden start/stops
- 45° cutting maneuvers
- 90° cutting maneuvers
- Combinations of agility drills
- Sport-specific plyometric training drills by weeks 12 to 16

Milestones for Progression to the Next Phase

- Full range of motion
- Quadriceps strength 80% or greater than opposite extremity
- Hamstring strength 110% or greater than opposite extremity
- Quadricep torque/body weight ratio 55% or greater
- Hamstrings/quadriceps ration 70% or greater
- Proprioceptive test equivalent to contralateral leg
- Functional testing 85% or greater to contralateral leg
- Pain-free knee

Phase V: Postoperative (weeks 16 to 22)

Clinical Pearls

The key goal in Phase V is returning patients to their preoperative level of sports or activity. Much of this also includes building confidence in their reconstructed knee. Continuing to progress strengthening, functional, proprioceptive, and sport-specific drills, all while increasing applied loads and difficulty will help your patients achieve these goals. The workhorse exercises of this phase include single leg squats and lunges in addition to sport-specific drills.

Goals

- Gradually returning the patient to full, unrestricted sports
- Maximizing leg strength and endurance
- Normalizing neuromuscular control
- Progressing skill training
- Continuing to build limb confidence

Management of Pain and Swelling

- Pain should be minimal to nonexistent at this point.
- Cryotherapy, electrical stimulation, and transcutaneous electrical neuromuscular stimulation (TENS) devices can be used when necessary.
- Narcotic pain medication should not be necessary at this point.
- Joint compression with a knee sleeve or ace wrap is the most frequently used modality.
- Knee sleeve can be discontinued but some patients psychologically feel more comfortable when wearing it.
- Ice for 20 minutes hourly and elevate lower extremity.

Techniques for Progressive Increase in Range of Motion

- Self-performed range of motion stretching exercises should be performed 4 to 5 times daily. There should be an emphasis on maintaining full, passive range of motion (full extension and full flexion).

Other Therapeutic Exercises

- Bicycle
- Straight leg raises (hip flexion, adduction, abduction, extension)
- Pool running (provided no wound healing problems); forward and backward running

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Hamstring curls
- Leg press
- Progress isometric strengthening program

Sensorimotor Exercises

- Continue balance training on a tilt board.
- Continue balance training with medicine ball throws.
- Continue perturbation training on single leg.

Open and Closed Kinetic Chain Exercises

- Lateral lunge step-overs
- Front and side lunges

- Lateral step-downs
- Front step-downs
- Wall squats
- Vertical squats
- Toe calf raises
- Stair-stepper machine

Techniques to Increase Muscle Strength, Power, and Endurance

- Stair-stepper machine
- Bicycle
- Walking program

Neuromuscular Dynamic Stability Exercises

- Biodex stability system
- Balance training on a tilt board
- Balance training with medicine ball throws
- Perturbation training

Plyometrics

- Can progress plyometric leg presses
- Continue other plyometric training drills

Functional Exercises

- Lunges with sport cord
- Progress running and agility training

Sport-Specific Exercises

- Cone drills
- Side shuffles
- Cariocas
- Sudden start/stops
- 45° cutting maneuvers
- 90° cutting maneuvers
- Combinations of agility drills
- Continue other plyometric training drills
- Sport-specific skill training (e.g., coming out of a 3-point stance for football lineman, changing direction from backpedal to sprint, etc.).

Criteria for Return to Sport

6-Month Time Point

- No knee effusion
- Full knee range of motion
- Quad atrophy less than 2 cm
- No more than 3 mm on Lachman test
- No more than a trace pivot shift
- Lysholm score > 75
- SANE score > 75
- No subjective sense of instability
- No difficulty with activities of daily living
- Knee extension and flexion at least 70% of normal
- Single-leg press at least 70% of normal
- Single leg squat possible

Specific Situations

- Contact athletes (e.g., football or hockey players) should first return to practice on a limited basis before full contact is allowed. Often, this can be achieved by allowing the athlete to participate in practice while wearing a noncontact (e.g., red colored) jersey.

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Athletes are encouraged to continue strength and agility exercises on their own to preserve strength, functional, and proprioceptive gains.

Exercises and Other Techniques for Prevention of Recurrent Injury

- Lateral box jumps
- Single leg hurdles
- Single leg lunges and squats

Evidence

Grinsven S, Cingel REH, Holla CJM, et al: Evidence-based rehabilitation following anterior cruciate ligament reconstruction. *Knee Surg Sports Traumatol Arthrosc* 18:1128–1144, 2010.

Following a bone-patellar tendon-bone autograft (BPTB) or four-stranded semitendinosus/gracilis tendons autograft (ST/G) anterior cruciate ligament (ACL) reconstruction, the speed and safety with which an athlete returns to sports (or regains the preinjury level of function) depends on the rehabilitation protocol. Considering the large differences in clinical and outpatient protocols, there is no consensus regarding the content of such a rehabilitation program. Therefore, we conducted a systematic review to develop an optimal evidence-based rehabilitation protocol to enable unambiguous, practical and useful treatment after ACL reconstruction. The results clearly indicated that an accelerated protocol without postoperative bracing, in which reduction of pain, swelling, and inflammation, regaining range of motion, strength, and neuromuscular control are the most important aims, has important advantages and does not lead to stability problems. Preclinical sessions, clear starting times, and control of the rehabilitation aims with objective and subjective tests facilitate an uncomplicated rehabilitation course. Consensus about this evidence-based accelerated protocol will not only enhance the speed and safety with which an athlete returns to sports, but a standardized method of outcome measurement and reporting will also increase the evidential value of future articles.

Gulotta LV, Rodeo SA: Biology of autograft and allograft healing in anterior cruciate ligament reconstruction. *Clin Sports Med* 26:509–524, 2007.

Excellent review article regarding the biology of anterior cruciate ligament healing written by experts in the field. (Level V evidence)

Howell SM, Deutsch ML: Comparison of endoscopic and two-incision technique for reconstructing a torn anterior cruciate ligament using hamstring tendons. *Arthroscopy* 15:594, 1999.

This study compared the differences in clinical outcome between an endoscopic (67 of 70) and two-incision (41 of

49) technique used to reconstruct torn anterior cruciate ligaments (ACL) using a double-looped semitendinosus and gracilis (DLSTG) graft. The postoperative treatment featured an aggressive rehabilitation protocol without a brace and allowed unrestricted sports participation 4 months after reconstruction. Age, sex distribution, duration from injury to surgery, and preoperative laxity were not significantly different between treatment groups.(Level III evidence)

Janssen RPA, Wijk J, Fiedler A, et al: Remodelling of human hamstring autografts after anterior cruciate ligament reconstruction. *Knee Surg Sports Traumatol Arthrosc* 19:1299–1306, 2011.

Human hamstring grafts showed typical stages of graft remodelling, which was not complete up to 2 years after ACL reconstruction. The remodelling process in humans was prolonged compared with the results obtained in several animal studies.

MacDonald P, Hedden D, Huebert D: Effects of an accelerated rehabilitation program after anterior cruciate ligament reconstruction with combined semitendinosus-gracilis and a ligament augmentation device. *AJSM* 23:588, 1995.

Forty patients undergoing ACL reconstruction using semitendinosus and gracilis autografts and a ligament augmentation device were retrospectively reviewed at minimum 20 months postoperatively to determine if accelerated rehabilitation was detrimental. Of the 37 patients available for follow-up, 34 had good-excellent results. The study concluded that early, accelerated rehabilitation of ACL reconstruction using this type of graft does not adversely affect outcome. (Level III evidence)

Majima T, Yasuda K, Tago H, et al: Rehabilitation after hamstring anterior cruciate ligament reconstruction. *Clin Orthop Relat Res* 397:370–380, 2002.

A prospective comparative study was conducted involving 62 patients to determine the effects and limits of accelerated rehabilitation on clinical outcome. The study focused on whether aggressive rehabilitation after anterior cruciate ligament reconstruction with the doubled semitendinosus and gracilis tendon autograft results in stretching the graft. A total of 30 patients had postoperative rehabilitation according to the current conservative protocol, and 32 patients had rehabilitation using an accelerated regime. Each patient was evaluated subjectively and objectively 36 months or more after surgery. Concerning the side-to-side difference in the anterior laxity, 87% of the patients in the conservative rehabilitation group had 3 mm or less laxity and 80% of the patients in the accelerated rehabilitation group had the same acceptable laxity. There was no significant difference between the two groups. Muscle torque was restored significantly earlier in the patients in the accelerated rehabilitation group than in the patients in the conservative rehabilitation group. Nine months after surgery, however, there were no significant differences in the torque between the two groups. Accelerated rehabilitation significantly increased the incidence of knee effusion during rehabilitation. This study showed that acceleration of postoperative rehabilitation could rapidly restore muscle strength without significantly compromising graft stability in anterior cruciate ligament reconstruction with the doubled hamstring tendon autograft. However, this study also showed that acceleration significantly increases the incidence of synovitis. Acceleration of postoperative rehabilitation has advantages and disadvantages for clinical outcome after anterior cruciate ligament reconstruction.

Wright RW, Preston E, Fleming BC, et al: A systematic review of anterior cruciate ligament reconstruction rehabilitation: Part I: Continuous passive motion, early weight bearing, postoperative bracing, and home-based rehabilitation. *J Knee Surg* 21:217–224, 2008.

Many issues regarding ACL reconstruction rehabilitation have been evaluated using randomized controlled trials. The methodologic quality of the studies reviewed is mixed. Most of the studies have some form of potential bias. This is especially true of the studies published prior to 2000, when many of the study quality issues were not yet recognized. Despite this, some reasonable conclusions can be made from the studies and used in developing an ACL reconstruction rehabilitation protocol. Early weight bearing appears beneficial and may decrease patellofemoral pain. Early motion is safe and may help avoid problems with later arthrofibrosis. Continuous passive motion is not warranted to improve rehabilitation outcome in patients and can avoid the increased costs associated with CPM. Minimally supervised physical therapy in selected motivated patients appears safe without significant risk of complications. Postoperative rehabilitative bracing either in extension or with the hinges opened for range of motion does not offer significant advantages over no bracing.

Wright RW, Preston E, Fleming BC, et al: A systematic review of anterior cruciate ligament reconstruction rehabilitation: Part II: Open versus closed kinetic chain exercises, neuromuscular electrical stimulation, accelerated rehabilitation, and miscellaneous topics. *J Knee Surg* 21(3):225–234, 2008.

Early weightbearing appears beneficial and may decrease patellofemoral pain. Early motion is safe and may help avoid problems with later arthrofibrosis. Continuous passive motion is not warranted to improve rehabilitation outcome in patients and can avoid the increased costs associated with CPM. Minimally supervised physical therapy in selected motivated patients appears safe without significant risk of complications. Until further studies are performed, protocols should use closed kinetic chain exercises in the first 6 weeks. Postoperative rehabilitative bracing either in extension or with the hinges opened for range of motion does not offer significant advantages over no bracing. Neuromuscular electrical stimulation, if deemed necessary for patients, should be instituted early in the postoperative period and should be of high intensity to achieve meaningful results. Accelerated rehabilitation appears safe, at least in the 5-month to 6-month time frame. Water-based therapy, stair climber, and slideboard exercise programs appear safe and may add variety if available for patients. Gait, proprioception, and psychological training may be of some benefit. Creatine, at least in the dosage and time frame used, offered no benefit. Restricting blood flow during rehabilitation sessions requires further studies before it becomes regularly prescribed by most clinicians. Despite more than 50 randomized controlled trials in the field, many questions remain, and further studies are warranted to continue to add evidence to our ACL reconstruction rehabilitation protocols.

Multiple-Choice Questions

QUESTION 1. When should bracing be discontinued?

A. 2 to 4 weeks
B. 16 weeks
C. 10 weeks
D. 12 weeks

QUESTION 2. Which of the following are not good treatments for postoperative pain in the immediate postoperative period?

A. Cryotherapy
B. TENS devices
C. Passive range of motion
D. Open chain exercises

QUESTION 3. Which of the following is not a goal for the immediate postoperative period?

A. Restore full passive knee extension
B. Reduce joint swelling
C. Reestablish voluntary quadriceps control
D. Return leg strength to normal

Answer Key

QUESTION 1. Correct answer: **A** (see Weeks 2 to 4)

QUESTION 2. Correct answer: **D** (see Weeks 0 to 2)

QUESTION 3. Correct answer: **D** (see Weeks 0 to 2)

BEYOND BASIC REHABILITATION: RETURN TO SOCCER AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

Jason L. Koh, MD, FAAOS, and Julie O'Connell, PT, DPT, OCS, ATC

Introduction

- Soccer demands near constant running, twisting, and pivoting activity while simultaneously handling the ball with the feet.
- Kicking and one-legged balancing are requirements, and jumping to trap or head the ball is an integral part of the game.
- Physical contact with other athletes during these activities and tackling is common, and field conditions can be quite variable.
- These are all key aspects of the sport that require particular attention during the rehabilitation of soccer players.

ASPECTS OF SOCCER THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- Ability to perform cutting, twisting and pivoting maneuvers with and without a ball
- Ability to perform extensive running activity with change of speed and direction.
- Ability to perform kicking activities of a ball
- Soccer requires jumping and landing on uneven surfaces in cleated shoewear.
- Ability to sustain and initiate contact with other athletes
- Ability to tolerate uneven surfaces with cleated shoewear

- Soccer (or football) is the most popular sport in the world, with an estimated number of over 250 million players[1].
- Anterior cruciate ligament (ACL) tears are common injuries in soccer players at all levels, from youth[2] to professional[3] athletes. The incidence of ACL injuries is quite high, with rates of 0.13 per 1000 exposures in male NCAA soccer players[4], and 4.9% to 6.2% at the professional level[5], with even higher rates for female athletes of up to 0.31 per 1000 exposures for female soccer players[4,6].
- The majority of ACL tears in soccer players are noncontact injuries[7], suggesting that neuromuscular factors may play a significant role in the etiology of these injuries.
- Multiple intervention programs have been used to attempt to decrease this incidence[8-21], with variable amounts of success. Several have demonstrated no difference in injury incidence[18]; others have demonstrated that appropriate training can substantially decrease the numbers of ACL injuries[8,10,11,13,14,21]. A recent systematic review[15] stated that evidence existed to recommend prevention programs for female athletes, but that insufficient data existed to support this conclusion for male athletes. It does appear that appropriately focused programs can be successful, even in a predominantly low income urban population[8].
- However, despite the presence of these various prevention programs, there is evidence that the overall incidence of ACL injuries has remained essentially unchanged[6], at least for women.[22]

- Since soccer is a sport that has near constant motion with extensive cutting, pivoting, and twisting, patients with ACL injured knees typically require reconstruction to return to play, but even after reconstruction, there have been challenges in returning to their previous level of activity.[3,23-25]
- Extensive physical rehabilitation, combined with psychological factors and confidence, is critical for athletes to return to competition.[26-30] Patients who undergo ACL reconstruction often have a prolonged course to return to full activity[23], with many patients not returning to soccer even at twelve months.[31,32]
- Eventual return to sports activity can be very high in some populations, such as European professional athletes[33], but many patients never return to their previous level of activity.[31,32,34]
- Many patients who do participate will leave the sport within several years.[31] Even in those who do return to sports activity, reinjury is common[35-40], with rates as high as 44%.[41] Recurrent tears of the reconstructed ligament or tears of the contralateral ACL are also common.[42] Given this information, the rehabilitation of ACL injured patients for soccer is particularly challenging and critical.

Literature

- A limited number of articles have discussed specifically the process and return to soccer after anterior cruciate ligament reconstruction.
- Return-to-sport criteria have typically been relatively non–sports-specific, with suggestions that hop tests and strength testing of at least 85% of the contralateral knee are necessary.[43]
- The Delware-Oslo ACL cohort study found that: "Hop tests conducted 6 months postoperatively statistically significantly predicted self-reported knee function ($p < .02$)"[44] Minimal other guidance has been provided for soccer.
- The return-to-sport rate after ACL injury is often an aggregate of multiple different athletic activities. Some authors have reported extremely high (94%) rates of return to soccer, but others have reported lower rates of 72%[24] or even 19%.[25] A recent paper found a 77% return to sport after injury in American Major League Soccer.[45]
- Persistent residual neuromuscular deficits[46] and abnormal kinematics[47] are not uncommon after anterior cruciate ligament reconstruction and may be related to lower levels of return to sport and repeat injury.[38]
- Increased knee abduction motion, asymmetry in internal hip rotation moment, asymmetry in knee extensor moments during a drop vertical jump, and deficits on single-legged postural assessment predicted a second injury with excellent sensitivity (92%) and specificity (88%).[47]
- Female athletes have been identified as having abnormal abduction angles and knee adductor moments and are particular risk for injury and reinjury.[48]
- Neuromuscular rehabilitation and control training can help address these issues.[20,49-51] Proprioception training, as in the PEP (Prevent injury and enhance performance) program pioneered by Dr. Bert Mandelbaum (head team physician for US Soccer), has been demonstrated to reduce the rate of ACL injury in soccer players by up to 50%.[14]
- Repeat ACL injuries or other lower extremity injuries are common after ACL reconstruction[40], and appropriate soccer-specific rehabilitation techniques that go beyond the basic rehabilitation program have been demonstrated to return patients to soccer effectively and decrease the risk of reinjury.[36,52,53]
- A randomized trial of coach-controlled rehabilitation involving return-to-match-play criteria has been demonstrated to be successful in reducing the rate of reinjury.[36]
- Sport-specific rehabilitation for soccer has shown improvements in patient function allowing a return to competition at an average of 185 days with a knee outcome survey-activity scale score of 96.[53]

Advanced Rehabilitation Program

- Match analysis shows that soccer involves substantial bursts of maximal activity with brief recovery periods, including running, jumping, pivoting, and cutting.[52]
- In addition, ball handling, contact, block, sliding tackles, and collisions on the ground and in the air are important elements of the sport.
- Enhanced rehabilitation techniques involving passing drills, shooting, dribbling, jumping, and sprinting. Block tackles, kicking into pads, and then simulated in-air contact and slide tackles are later incorporated to bring athletes back to a level where they can return to full competition.
- Our principles for athletes for return to play include both physical and psychological preparedness.
- Physical preparedness includes strength, flexibility, agility, and power; coupled with ball-specific and live contact activity. This can be done through self-report on a scale, such as the Tegner Activity Scale.[65] This scale grades activity related to ability to perform work and sport function. Also, it is important to compare returning athletes to their health counterparts in measures, such as maximum vertical jump, ball-shooting, 30-meter sprint, and yoyo intermittent endurance run.[66]
- Psychological preparedness can be assessed when watching the athlete participate in sport-specific activities and looking for apprehension during specific drills. The Tampa Scale for Kinesiophobia (TSK-11) is a self-report questionnaire used to assess pain-related fear of movement related to reinjury. The TSK-11 has 11 items, ranging with scores from 11 to 44. Higher scores are associated with higher kinesiophobia with worse self-reported knee function and a lower rate of return to sport. Characterization is made into two categories of potential coper and noncopers and the testing is done preoperation, after postoperative treatment, at 6 months postoperatively and at 12 months postoperatively.[67]

- Rehabilitation after ACL injury for soccer involves several phases, initially starting with clinic and gym sessions, followed by on field rehabilitation and progressive advancement of soccer-specific activity.
- Progression is criterion-based, rather than according to a strict timeline, and should be individualized to a specific athlete's ability to meet goals. Our program is evidence-based as much as possible and reflects the best available knowledge at this time for rehabilitation for ACL injured patients to return to soccer.
- We acknowledge the significant contribution of Dr. Lynn Snyder-Mackler and her group in developing a criterion-based rehabilitation program, particularly as it relates to soccer players recovering from ACL injuries[53-55], Drs. Holly Silvers and Bert Mandelbaum for their work with PEP[14,56], and the insight of Bizzini et al.[52,53] in training methods.

Phase I: Early Postoperative Program (weeks 0 to 6)

- Initial postoperative goals during the first 6 weeks are to control pain/swelling, to improve ROM, to achieve quadriceps activation, and to progress to full activities of daily living, including reciprocation on stairs and normalized gait.
- It is critical to obtain full knee extension (equivalent to the contralateral side) in the first 2 weeks, since extension loss has been associated with significant limitations of function and quadriceps inhibition[57-59] and is not associated with increased laxity. Prone hangs or use of an extension strap are useful to help obtain extension.
- Flexion should be at least 90° within the first week, and full flexion should be obtained by 6 to 8 weeks. This can be achieved by doing heel slides in supine, sitting or with feet on wall. Patella, patella tendon, and portal site mobilization (as incisions tolerate) are helpful to restore normal joint motion, as is use of a stationary bicycle.
- Quadriceps activation activities should begin immediately, with quadriceps contraction starting postoperatively day 1. High intensity neuromuscular electrical stimulation (NMES) has been demonstrated to improve quadriceps function[49,60] and can be initiated and progress until quadriceps strength is at 80% of the contralateral leg.
- Standing wall slides, step-ups, and other closed chain exercises in a pain-free range are typically used and may have lower graft stresses[61], although use of open chain exercises from 45° to 90° also appear to be safe.[62,63]
- Eccentric strengthening exercises starting at 3 weeks between 20° to 60° have been demonstrated to substantially (2 times) increase quadriceps muscle volume and also increase strength.[64]
- The initial goal is to achieve a straight leg raise without an extensor lag by 2 weeks, and 65% of quadriceps limb symmetry index (LSI) of opposite side by 6 weeks.[65]

FIGURE 32-32. Bridging with adduction via soccer ball squeeze.

- The use of a functional brace once straight leg raising is demonstrated can assist with athlete confidence postoperatively.
- Maintenance of cardiovascular fitness is important and we suggest use of an upper body ergometer, (arm bike), elliptical, or swimming.
- In addition to sagittal plane exercises, it is essential to address frontal plane stability including use of hip adductors and hip abductors, and this can be achieved by doing straight leg raises and isometric adductor squeezes of a soccer ball (Figure 32-32). Resisted lateral band walking is essential for gluteus medius stability.
- The transverse plane needs to be emphasized as well, including resisted side-lying hip external rotation and internal rotation.
- As described by PEP[14,56], the strengthening exercises that should be emphasized include walking lunges, Russian hamstrings, and single-toe raises. PEP also recommends an extensive lower extremity stretching program including calf stretch, quadriceps stretch (Figure 32-33), hamstring stretch, inner thigh stretch, and hip flexor stretch.
- In a desire to return to soccer, the Federation Internationale de Football Association has put together a complete warmup program related to soccer players called FIFA-11+, which has elements related to running, strength, plyometrics, and balance and strength activities, such as element #7 the bench, #8 the sideways bench, #9 hamstrings can be initiated here.[68,69]

FIGURE 32-33. Single-leg standing balance with contralateral foot on ball and movement forward and backward.

- The focus of strengthening the uninvolved leg must be addressed as well to create symmetry.

Goals (Adapted from University of Delaware Practice Guidelines[55])

Immediate Postoperative Phase (week 1)
- Achieve 0° to 90° PROM/AROM
- **Essential to achieve full knee extension to 0°.
- Ability to perform an active quadriceps contraction
- Achieve WBAT gait with proper heel strike to toe off
- Pain on VAS scale of less than 5 and trace swelling[28]

Weeks 2 to 4
- Achieve 0° to 110° PROM/AROM
- Ability to perform a straight leg raise without quad lag
- Normalizing gait with full knee extension at heel strike during gait
- Ability to climb stairs reciprocally

Weeks 4 to 6
- Achieve 0° to 130° of PROM/AROM
- Achieve 60% of quadriceps strength of uninvolved leg
- Normalized walking gait

FIGURE 32-34. Single-leg standing balance with inside of foot passing motion.

Phase II: Late Postoperative/ Transitional Phase (weeks 6 to 12)

- This phase is characterized by increasing intensity and duration of exercises, running progression, as well as the addition of soccer-specific activities including neuromuscular training and ball handling.
- A criterion-based progression for advancement is used, where the athlete may advance to running if there is a minimum of 80% quadriceps strength of LSI compared to contralateral extremity, trace effusion,[28] and no soreness.
- Soreness rules, such as in Box 32-1, and the absence of an effusion can guide advancement through a walk-to-run straight ahead program. This is initiated on a treadmill in a controlled speed environment with a basis of 10 minutes per mile pace. The program begins with walking 10 minutes and running 5 minutes and repeating twice. This progression is repeated every other day. The ratio is then decreased walking time and increased running time based on pain and swelling until full running is achieved for 2 miles or 20 minutes. The goal would be to increase distance and frequency with intensity as the third and final variable to increase. The progression occurs within a 4 to 6 week time period.
- Neuromuscular training for lower-extremity stabilization are also introduced in weightbearing positions starting with static and progressing to dynamic and reactive exercises.[65] Single-leg balance exercises can be performed when holding a ball, when throwing ball to a partner, or when a partner provides perturbations to you. Perform for 30 seconds and then compare to uninvolved side and then repeat twice. Squatting with toe raises, walking lunges, and one leg squats can also be performed as described in the FIFA11+ program[68,69] (Figures 32-33 and 32-34).
- These activities have shown to significantly improve function at 6 months and 1 year after surgery. The athlete is encouraged to begin ball-handling exercises including bouncing and juggling the ball and gentle passes with the internal and external sides of the foot.
- Gentle plyometric activities are started emphasizing quality of movement and landing, heading the ball is practiced once proper take-off, and landing techniques can be demonstrated.

BOX 32-1 Soreness Rules

No soreness	Progress
Soreness next day	Progress or hold depending on if discomfort requiring medication
Soreness > 2 days	Drop down
Soreness that goes away during session	Progress

Goals

Weeks 6 to 8
- Achieve full AROM.
- Achieve 80% of quadriceps limb symmetry index (LSI) as compared to contralateral side.
- Trace swelling. Effusion can be assessed by a stroke test and graded on a 5-point scale (none, trace, 1+, 2+ and 3+)[28]

Weeks 8 to 12
- Functional strength progression to 100% of quadriceps strength as compared to LSI of contralateral extremity leg

TIMELINE 32-5: :Return to Soccer After Anterior Cruciate Ligament Reconstruction

PHASE I (weeks 0 to 6)

- Weeks 0-2: Early Postop Phase
- Goals: Control pain/swelling; achieve quadriceps contraction
- AROM/PROM including heel slides, wall slides, and prone hang
- Mobilizations for patella, portals and patellar tendon
- Quadriceps strengthening with quad sets (NMES if necessary), TKE from 45°–90°, SLR, mini-squats
- Gait training
- Stair training
- Cardiovascular conditioning on upper body ergometer
- Ice for swelling management
- Ankle pumps in elevated position
- Weeks 2 to 6: Intermediate Postop Phase
- Goals: Achieve full extension and flexion to 110°, reciprocal stair climbing; begin frontal plane stability exercises; focus on neuromuscular control of lower extremity
- AROM/PROM to achieve 110° of knee flexion then progress to stationary bicycle and 0° of knee
- Mobilizations for patella, portals, and patellar tendon
- Quadriceps strengthening (NMES if necessary) followed by quad stretching
- Lower extremity strengthening with frontal plane emphasis for soccer ball adductor squeeze, and side-lying SLR
- Resisted lateral band walking
- Hamstring strengthening with hamstring curl and dead lift position followed by hamstring stretch
- Hip ER strengthening with clam shell exercise
- Gluteus maximus strengthening with prone SLR and bridging
- Calf strengthening with calf raises followed by calf stretch
- Single-leg standing balance and neuromuscular training exercises, such as a cone pickup
- Cardiovascular conditioning including elliptical and treadmill including retro
- Return to strengthening uninvolved leg

PHASE II (weeks 6 to 12)

Weeks 6 to 8: late postop phase

- Goals: Achieve full AROM; achieve 80% of quadriceps strength of uninvolved leg; trace swelling
- Continue progression of previous exercises
- Quadriceps strengthening with lunges in forward, lateral, and diagonals
- Eccentric quadriceps strengthening with step-downs program
- Frontal plane progression with lateral step-downs activities
- Core strengthening
- Lower extremity flexibility program

Weeks 8 to 12: transitional phase

- Goals: Increase intensity and duration of exercises; running progression
- Running progression begins:
  - A walk-to-run straight ahead program is initiated on a treadmill in a controlled speed environment with a basis of 10 minutes per mile pace for walking 10 minutes and running 5 minutes and repeating twice and repeating every other day.
  - The ratio can decrease walking and increase running based on pain and swelling until full running is achieved.
  - The goal would be to increase distance and frequency with intensity as the third and final variable to increase.
  - The progression occurs within a 4–6-week time period.

PHASE III (weeks 12 to 24)

Weeks 12 to 16: return-to-sport criteria

- Goals: Neuromuscular training and return to ball specific training; hop tests are performed if 80% of quadriceps strength index has been reached; hop tests include single hop, x-hop, triple hop, and timed hop
- For the on-field phase: On-field functional training progression on grass field with and without ball in molded cleats with progression to studded cleats; successful accomplishment of tasks allows for continued progression
  - straight ahead running without the ball in running shoes with progression to cleats and increasing speed
  - straight ahead dribbling with the ball in cleats with speed variations and stop and start
  - diagonal/backward running without the ball in cleats
  - Change of speed/direction with running without ball in cleats
  - Change of speed/direction with dribbling the ball
  - Initiate jumping and landing drills without the ball in running shoes and progress to cleats

Weeks 16 to 20: on field progression

- Goals: Aerobic/anaerobic fitness training intensity for to return to soccer activity
- Two-footed jumping and progression to one-footed jumping/landing in cleats
- Passing of a soccer ball at short distance with progression to longer distances and higher intensities with inside of foot/outside of foot and striking or shooting of ball
- Dribbling a ball beginning in a straight line and increasing speed and increasing change of direction using instep and outstep
- Partner passing and running onto a ball forward and lateral

Weeks 20 to 24

- Goals: Return to sport should include at least 90% of quadriceps maximal volitional isometric contraction and repeated and timed hop of 85% of the uninvolved side
- Practicing corner kicks, free kicks, dribbling, shooting, including quick change of direction during pass or volley.
- Progression to small sided 1 vs. 1, and 3 vs. 3 live soccer drills with contact
- Progression towards 11 vs. 11 high-intensity soccer including tackling and contact.
- Full cardiovascular anaerobic and aerobic tolerance to complete 90 minutes of soccer
- Ability to achieve preinjury status of fitness testing.

FIGURE 32-35. Single-leg standing balance with contralateral ball hold and then switch to contralateral limb.

- Balance and proprioceptive training with ability to maintain single leg balance for 60 seconds (Figure 32-35).
- Running progression on a treadmill in running shoes beginning with walk-to-run program straight ahead

Phase III: On-Field Phase (weeks 12 to 24)

- This phase is characterized by a progression of function and also increasing familiarity with soccer-specific activities to prepare the athlete physically and psychologically for a return to full soccer activities.
- The criteria to progress to an increase in activity are determined by having no physiologic changes in knee function, such as ROM or swelling changes, and no qualitative apprehension behavior demonstrated during functional progression as determined by a medical practitioner.
- Minimum criteria for progression to the on-field phase includes at least 80% quadriceps index, no instability or giving way, minimal pain, or effusion, and full or near full range of motion, as well as successfully being able to run without a limp.
- Hop tests are performed when 80% LSI has been reached. The authors describe the hop sequence as including single hop, crossover-hop, triple hop, and 6-meter timed hop.
- The elements of the plyometric portion of the FIFA-11+ program can be initiated with consisting of element #12, which is jumping vertical with knees flexed to 90° and repeating for 30 seconds and doing 2 sets followed by #12.2, which are lateral jumps from supporting leg 1-meter to the side and landing on the contralateral limb and holding for 1 second and repeating for 30 seconds for 2 repetitions. The #12.3 box jump is described as drawing a cross on the ground and jumping forward, backward, side to side, and diagonally across the cross for 30 seconds and repeating 2 times.[68,69]
- On-field progression (preferably on a well-maintained grass field) initially starts without the ball with molded cleats with progression to studded cleats.
- Initial activity (weeks 12 to 16) starts with running drills beginning with running shoes in a straight line on a grass field, with gradual increases in speed and with addition of cleats and the ball. Based on the FIFA-11+ program, running activities include straight ahead, hip out (ER position) and hip in (IR position), and elements of #13 running across the pitch at 75% to 80% acceleration, #14 bounding with 6 to 8 high steps.[68,69]
- Following successful completion of this figure-of-8 runs, followed by diagonal/backward running and changes of direction with cleats without the ball, light jumping and landing can proceed. Recommendations would be to set up 6 cones that are 5 to 6 meters apart and run forward, stop, and run backwards, then proceed to each cone. This could be repeated 3 times. A 30-meter sprint is also recognized as an appropriate training for conditioning for healthy soccer players where there would be 3 minutes in between and then repeat 3 times.[66] Also the #14 plant-and-cut of the FIFA 11+ program could begin, which includes 4 to 5 steps straight ahead followed by 5 to 7 steps at 80% to 90% acceleration to the right and changing directions to the left and going across the pitch and repeating twice.[68]
- As proficiency is demonstrated, increased intensity of speed, distance, repetitions, and turns can be implemented. PEP includes a forward run with 3-step deceleration, lateral diagonal runs, and bounding runs as important elements of agility as related to soccer players.
- During weeks 16 to 20, increased intensity for aerobic/anaerobic fitness is progressed. Fitness testing in soccer is measured with 30-meter sprint test, which is performed with a 3-minute rest in between each session and repeated 3 times as well as yoyo endurance test (also called a beep test), which is to perform a series of 20-meter shuttle runs at a pace set by an audio metronome, with a standard rest interval determined. The speed is progressively increased until the player cannot keep up with beep speed. A VO_2 max test can also be used.[66]
- Two-footed jumping with progression to one-footed jumping in cleats.
- Passing drills using the inside and outside of the foot, starting with short distances, can progress to longer distances and higher velocity. Passing and shooting on the laces can begin once confidence in side footing is established (Figure 32-36).
- Dribbling, starting with straight-line control and progressing to turns and instep/outstep control should be mastered, followed by lateral dribbling, increasing speed, and changing direction. Partner passing and running onto a ball forward and lateral can occur.
- Weeks 20 to 24 are characterized by increased intensity including running rotations, practicing corner kicks,

FIGURE 32-36. Passing and shooting of ball with involved extremity.

free kicks, and shooting, and quick sharp turns on receiving a pass or volley (Figure 32-37).
- There is a progression to small sided live soccer drills with contact (3 vs. 3, 1 vs. 1) that increase in intensity, with progression towards 11 versus 11 high-intensity soccer.
- Tackling and contact drills can occur in preparation for competition.
- Intensity of cardiovascular activity including anaerobic training should occur to return the athlete to full cardiovascular tolerance to complete 90 minutes of soccer.
- We also recommend ability to achieve preinjury status of fitness testing. This can be performing a 30-meter sprint test or the yoyo intermittent endurance run or the VO_2 max test.[66]
- Return to sport should include at least 90% of quadriceps limb symmetry index (LSI) of the opposite side quadriceps and repeated and timed hop of 85% of the uninvolved side.

FIGURE 32-37. Example of receiving a volley with the involved extremity at knee or could be at foot as well.

- Return can include reduced team training without contact; full team training with contact; friendly games with limited minutes, and return to competition, with gradual increases in duration. The reintegration process involves both a physical and mental progression for the athlete, and contact drills can help the athlete regain confidence for full sports activity.
- In general, we have found that high-level soccer players can return to previous levels of sport and ability, but this is typically a prolonged process with early return occurring at 5 to 6 months after injury.

Specific Criteria for Progression to the Next Stage to Determine Readiness for Soccer

- The criteria to progress to an increase in activity are determined by having no physiologic changes in knee function, such as ROM or swelling changes, and described as a potential coper versus a noncoper on the TSK-11.[67] Soreness rules should be stated and followed.[55]

Specific Criteria for Releasing an Athlete to Unsupervised Complete Participation in Soccer

- Successful completion of phased rehabilitation without physiologic signs of pain, swelling, instability, limp, or psychological apprehension provide confidence for provider to release back to team-based activities.[36]

Recommended Ongoing Exercises

- Success related to return-to-play is reliant upon maintaining functional strength, balance, flexibility, and cardiovascular fitness. These activities need to be completed with and without a ball and in training environments, such as on a grassy surface, with cleated shoes to simulate function necessary with activity.
- Exercises that should be maintained include closed chain strengthening (e.g., squats and lunges), jumping and landing activities (e.g., single-leg hop), and frontal plane mechanical training including cutting and side-to-side activities.[48]
- FIFA-11+program for general warmup for soccer-specific exercises should be used as well.[68,69]

Evidence

Adams D, Logerstedt D, Hunter-Giordano A, et al: Current concepts for anterior cruciate ligament reconstruction: A criterion-based rehabilitation progression. *JOSPT* 42:601–614, 2012.

This is an update of previously published, evidence-based guidelines for the management of patients after anterior

cruciate ligament reconstruction from some of the acknowledged experts in the field. (Level V evidence)

Arendt E, Dick R: Knee injury patterns among men and women in collegiate basketball and soccer: NCAA data and review of literature. *Am J Sports Med* 23:694–701, 1995.

This important study used the NCAA injury surveillance system to evaluate anterior cruciate ligament injuries over a 5-year period and demonstrated that female soccer players had an ACL tears rate of 0.31 per 1000 exposures versus 0.13 in males. (Level II evidence)

Bizzini M, Hancock D, Impellizzeri F: Suggestions from the field for return to sports participation following anterior cruciate ligament reconstruction: Soccer. *JOSPT* 42:304–312, 2012.

This is a description of soccer-specific neuromuscular control and conditioning for an effective return to sports from the FIFA Medical Assessment and Research Center, Zurich, Switzerland and the physical therapist of the English National Team and former therapist for Chelsea and Leeds football clubs in the English Premier League. (Level V evidence)

Brophy RH, Schmitz L, Wright RW, et al: Return to play and future ACL injury risk after ACL reconstruction in soccer athletes from the Multicenter Orthopaedic Outcomes Network (MOON) group. *Am J Sports Med* 40:2517–2522, 2012.

In this prospective cohort study, 100 soccer players were contacted about return to play. A total of 72% initially returned to soccer, but only 36% were still playing at an average follow-up of 7.0 years, and 20% of female players had additional ACL surgery (compared to males, 5.5%). (Level III evidence)

Della Villa S, Boldrini L, Ricce M, et al: Clinical outcomes and return to sports participation of 50 soccer players after anterior cruciate ligament reconstruction through a sport-specific rehabilitation protocol. *Sports Health* 4:17–24, 2012.

This award-winning paper followed 50 patients who underwent a soccer-specific rehabilitation protocol that included specific on-field activities. Patients had significant improvements in activity, muscle strength, and aerobic threshold during on-field rehabilitation; and average time to return to competition was 185±52 days. (Level IV evidence)

DiStasi S, Logerstedt D, Gardinier E, et al: Gait patterns differ between ACL-reconstructed athletes who pass return-to-sport criteria and those who fail. *Am J Sports Med* 40:1–9, 2013.

A total of 42 patients were evaluated for return-to-sports criteria at 6 months; 48% passed and those patients demonstrated statistically significant differences between limbs. (Level III evidence)

Hagglund M, Walden M, Ekstrand J: Lower reinjury rate with a coach-controlled rehabilitation program in amateur male soccer: A randomized controlled trial. *Am J Sports Med* 35:1433–1442, 2007.

A study where 24 teams were randomized either into a coach-controlled rehabilitation group (n = 282) or a control group (n = 300). The rehabilitation program consisted of a 10-step progressive rehabilitation protocol with return-to-play criteria. In the intervention group, the r-injury rate was significantly less (11%) than the control group (29%), with the greatest risk reduction for lower extremity injuries (75%). (Level I evidence)

Logerstedt D, Grindem H, Lynch A, et al: Single-legged hop tests as predictors of self-reported knee function after anterior cruciate ligament reconstruction: The Delaware-Oslo ACL cohort study. *Am J Sports Med* 40:2348–2356, 2012.

Article discussing when 120 patients were treated with ACL reconstruction and underwent single-legged hop testing. The crossover hop and 6-meter timed hop symmetry index at 6 months predicted self-reported knee function and could discriminate those patients who had good function. Preoperation testing did not predict postoperative outcomes. (Level III evidence)

Mandelbaum BR, Silvers HJ, Watanabe DS, et al: Effectiveness of a neuromuscular and proprioceptive training program in preventing anterior cruciate ligament injuries in female athletes: 2-year follow-up. *Am J Sports Med* 33:1003–1010, 2005.

A key article following 1885 female competitive youth soccer players prospectively enrolled in a sport-specific neuromuscular and proprioceptive performance program (PEP) compared to 3818 age- and skill-matched controls in the same league over a 2-year period. During the first season, there was an 88% decrease in anterior cruciate ligament injury in the enrolled subjects; in the second season, there was a 74% reduction in anterior cruciate ligament tears. (Level II evidence)

Stearns K, Pollard C: Abnormal frontal plane knee mechanics during sidestep cutting in female soccer athletes after anterior cruciate ligament reconstruction and return to sport. *Am J Sports Med* 41:918–923, 2013.

Study where12 female soccer players with a history of anterior cruciate ligament reconstruction were compared to a control group and who demonstrated increased knee abduction angles and peak knee adductor moments, despite return to sports. (Level III evidence)

Multiple-Choice Questions

QUESTION 1. In the Brophy et al. study of 100 soccer players returning to play after ACL, what percentage of players initially returned to soccer?

A. 36%
B. 20%
C. 72%
D. 80%

QUESTION 2. Which of the following is not an element of the FIFA 11+ warmup for soccer players?

A. Strengthening exercises
B. Flexibility exercises
C. Running
D. Plyometric exercises

QUESTION 3. All of the following exercises are elements of PEP EXCEPT:

A. Walking lunges
B. Russian hamstrings
C. Single-toe raises
D. Squats

QUESTION 4. What measure is available to assess the psychological preparedness of an athlete to return to sport?

A. The Tegner activity scale
B. The Tampa scale for kinesiophobia
C. PEP
D. FIFA 11+ program

QUESTION 5. When has eccentric strengthening from 20° to 60° been shown to increase quadriceps muscle volume (2 times) and to increase muscle strength after ACL reconstruction

A. 3 weeks
B. 4 weeks
C. 6 weeks
D. 12 weeks

Answer Key

QUESTION 1. Correct answer: **C** (see Evidence, Brophy et al.)

QUESTION 2. Correct answer: **B** (see Phase I: Early Postoperative Program)

QUESTION 3. Correct answer: **D** (see Phase I: Early Postoperative Program)

QUESTION 4. Correct answer: **B** (see Advanced Rehabilitation Program)

QUESTION 5. Correct answer: **A** (see Phase I: Early Postoperative Program)

POSTOPERATIVE REHABILITATION AFTER ANATOMIC ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

Kellie K. Middleton, MPH, Bart Muller, MD, Stephen J. Rabuck, MD,
James J. Irrgang, PT, PhD, ATC, FAPTA, and Freddie H. Fu, MD

Indications for Surgical Treatment

- Participation in high-demand sports that involve cutting, jumping, pivoting, and quick deceleration.
- Heavy work and physically demanding occupations.
- Persistent knee instability in spite of rehabilitation.
- Multiligamentous and concomitant injuries to additional structures within the knee.
- The timing of ACL reconstruction surgery has a strong influence on postoperative knee stiffness and rehabilitation. To decrease the risk of postoperative stiffness and delayed rehabilitation, surgery should be performed when pain and swelling are well controlled, and when gait and range of motion have been restored to normal or near normal, and the patient can perform a good quad set and straight leg raise without a quadriceps lag.

Brief Summary of Surgical Treatment

Patient Set-Up

- Regional anesthesia when possible: femoral or sciatic nerve blocks or spinal anesthesia.
- A thorough exam under anesthesia compared to the contralateral knee is critical.
- Well-padded tourniquet placed high on the operative extremity. Positioned within leg holder to allow flexion greater than 125 degrees (Figure 32-38).

FIGURE 32-38. Operative extremity positioned in a well-padded tourniquet and a leg holder, which allows flexion angles greater than 125°.

Individualized Anatomic ACL Reconstruction: Major Steps in Technique

- Three portal techniques: A high anterolateral (AL) portal, an anteromedially placed central portal (CP), and an accessory anteromedial (AM) portal (Figure 32-39).
- Diagnostic arthroscopy is performed to characterize ACL rupture and associated pathology.
- Intraoperative measurements of the native ACL anatomy help determine operative technique. (Figure 32-40)
  - A patient's notch and insertion site size are variable and do not correlate to the patients height, weight, or BMI.
  - In cases with a smaller notch or insertion site a single bundle technique is preferred. In patients with a larger notch and insertion site, a double bundle technique is preferred.
- Anatomic SB ACL Reconstruction:
  - A single femoral tunnel is centered within the native femoral footprint.
  - The tibial tunnel is centered within the native footprint with the tibial guide set to 55 degrees.

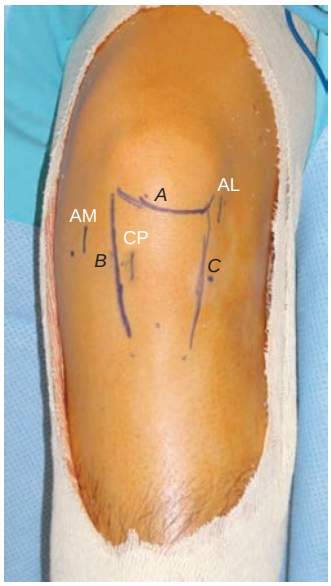

FIGURE 32-39. Three-Portal Arthroscopic Technique: High anterolateral (AL) portal, an anteromedially placed central portal (CP), and an accessory anteromedial (AM) portal. Patellar anatomic landmarks and joint line are used to make the incisions. (**A**) Inferior pole of the patella. (**B**) Medial border of the patella tendon. (**C**) Lateral border of the patella tendon.

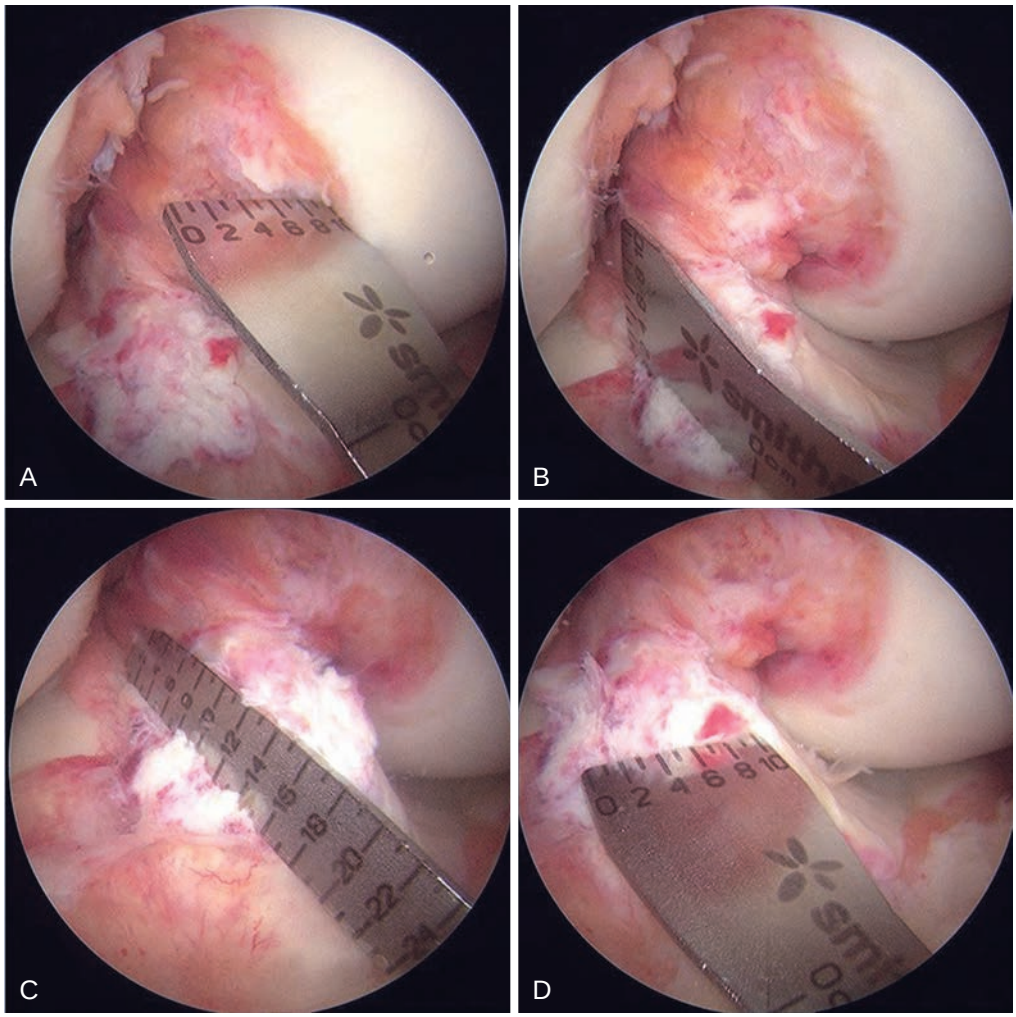

FIGURE 32-40. Intraoperative measurements with an arthroscopic ruler are used to determine operative technique. (**A**) Notch width. (**B**) Notch height. (**C**) Tibial insertion site length. (**D**) Tibial insertion site width.

  - The graft is tensioned and fixed in 10 to 15 degrees of flexion.
- Anatomic DB ACL Reconstruction:
  - The PL femoral tunnel is drilled first with the knee held in 110 degrees of flexion.
  - The tibial PL and AM tunnels sequentially drilled, being careful to avoid tunnel convergence.
  - Next, the femoral AM tunnel is drilled via AM/PL tibial tunnels or the AMP as the patient's anatomy dictates.
  - The AM tunnel can be drilled through either the PL tibial tunnel (50% of the time), or the AM tibial tunnel (10% of the time).[1]
  - Sequence of graft passage: The PL graft is passed before AM graft.
  - The PL bundle graft is tensioned and fixed in full extension.
  - AM graft is tensioned and fixed in 45 degrees of flexion.
- Graft Fixation:
  - Standard fixation techniques include tying over a post, suspensory fixation (i.e. endobutton), and interference screws.

Factors That May Affect Rehabilitation

Anesthetic

- Patients may complain of pain and weakness in the upper portion of the thigh secondary to the regional anesthesia injections. This pain is transient and should not interfere with normal rehabilitation protocol.
- Regional analgesia may wear off 8 to 24 hours after the case. A careful transition to oral analgesics is important to facilitate early rehabilitation.

Surgical

- Graft choice:
  - Allograft ACL reconstruction requires slower rehabilitation and return to sports to allow for slower graft incorporation and healing.[2,3]
  - Bone plugs facilitate a more rapid osseous integration within bone tunnels when compared to soft tissue grafts.
- Anatomic Placement of the Grafts:
  - An anatomically placed ACL experiences more forces than a nonanatomically placed ACL.[4] The

increased forces can result in early rupture and a careful rehabilitation must be followed.
- Postoperative donor-site morbidity and anterior knee pain:
  - Harvest of an autograft can lead to specific postoperative donor-site morbidity.
  - Anterior knee pain and decreased sensation are associated with patellar tendon autografts.[5]
  - Hamstring autografts have less anterior knee pain[6–8] but may produce weakness at higher flexion angles.[9]
- ACL reconstruction in association with concomitant injuries:
  - Modifications must be made to the rehabilitation program following repair or reconstruction of menisci or in cases of multiligamentous injury.
  - A higher incidence of stiffness is associated with MCL repair.
  - Chondral lesions require a more careful rehabilitation program.
- Tourniquet use:
  - Prolonged tourniquet use may affect lower limb strength.[10]
- Meniscal surgery
  - Meniscal surgery may require a modified rehabilitation protocol depending on surgeon and rehabilitation specialist preference.
  - Following meniscal repair, hyperflexion should be restricted. Immobilization at or near full extension (10° to 20° flexion) has been shown to allow for better approximation of longitudinal tears.[11]
  - Either partial weightbearing or no weightbearing is another common modification of ACL rehabilitation protocols following meniscal surgery.
  - Following meniscus repair, flexion is limited to 90° the first 4 to 6 weeks after surgery.

Before Surgery: Overview of Goals, Milestones, and Guidelines[3]

The goals of preoperative rehabilitation (or prehabilitation) are to control pain and swelling, restore normal range of motion, achieve a good quad set and the ability to perform a straight leg raise without a lag, and develop muscle strength sufficient for normal gait and activities of daily living (ADL). Additionally, prehabilitation can be used to mentally prepare the patient for surgery and the postoperative rehabilitation protocol thereafter.

Immobilization

- For isolated ACL rupture bracing is not routinely necessary.
- Crutches may be necessary for assistance immediately after injury. Once pain and swelling have resolved, quadriceps strength is sufficient for a normal gait and the patient can demonstrate a normal gait without a flexed knee at heel strike and mid-stance, assistive devices may not be discontinued.
- Patient should bear weight as tolerated.

Pain and Swelling

- Ice and elevation along with nonsteroidal antiinflammatory drugs (NSAIDs).
- NSAIDs should be continued for 7 to 10 days following acute injury.

Restoration of ROM and Strength

- Quadriceps function can be inhibited by post-injury disuse and the presence of an effusion.
- Preoperative ROM exercises and quadriceps strengthening exercises (e.g., quad sets, straight leg raises) should be started as soon as tolerated. These exercises will help to improve quadriceps strength and reduce the effusion.
- Aquatic therapy can be initiated for strengthening if normal weightbearing is not tolerated.

Prehabilitation exercises should be discontinued if pain and swelling worsen as a result.

GUIDING PRINCIPLES OF POSTOPERATIVE REHABILITATION

- Understand surgical technique, graft choice, and fixation method.
- Understand graft healing and adjust progression of functional activities accordingly.
- Understand the implications of associated pathology and multiligamentous injuries (e.g., meniscal tears, posterior cruciate and collateral ligament injuries, chondral damage).
- The importance of immediate mobilization in recovery of strength and ROM.
- Guidelines for return to sports and prevention of future ipsilateral and contralateral knee injury.

This chapter describes postoperative ACL reconstruction guidelines that are divided into six phases. Though approximate timeframes within each phase are mentioned, patient progression depends on the clinical impression of the surgeon and or rehabilitation specialist.

Phase I: Immediate Postoperative Period (days 0 to 14)

Clinical Pearls

- The highest incidence of knee stiffness occurs if ACL reconstruction surgery is performed in the presence of knee swelling, pain, limited range of motion, and the inability to perform a good quadriceps contraction. The risk of developing a stiff knee after surgery can be significantly reduced if the surgery is delayed until after the acute inflammatory response has subsided (e.g., reduced pain

[3]*Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

and swelling, a near normal range of motion, a good quadriceps contraction, and normal or near-normal gait pattern has been re-established.
- Restoring ROM in an early phase decreases pain and prevents patellofemoral problems. It also prevents alterations in gait, quadriceps atrophy, scar formation, capsular contractions, and adverse chondral changes.

Goals

1. Control postoperative pain and swelling.
2. Protect the healing structures.
3. Obtain full passive and active knee extension symmetrical to the noninvolved side
4. Obtain 90° to 120° of flexion, provided a meniscus repair has not been performed. If a meniscus repair was performed, flexion is limited to 90° for the first 4 to 6 weeks.
5. Maintain or restore patellar mobility, especially superior glide which is necessary for full active extension of the knee.
6. Re-establish quadriceps control so that the patient can perform a good quad set, resulting in a full quadriceps contraction and superior migration of the patella and the ability to perform a straight leg raise without a quadriceps lag.

Protection

- Postoperative immobilization using a brace locked in full extension and axillary crutches to assist with weight bearing and encourage full extension.
- If no concomitant meniscal repairs, the brace may be unlocked for ambulation after the first week.
- Concomitant meniscal repairs require that the brace be locked in full extension for 4 to 6 weeks postoperatively.
- After unlocking the brace, weight bearing as tolerated is permitted with crutches during ambulation emphasizing a normal heel-toe gait pattern.

Management of Pain and Swelling

- Primary approach utilizing a combination of cryotherapy, compression, and elevation.
- A multimodal approach with oral pain medication in addition to nonsteroidal antiinflammatory drugs (NSAIDs) should be instituted to minimize inflammation.
- Early active and active-assisted motion exercises.[12]

TIMELINE 32-6: **Postoperative Rehabilitation After Anatomic Anterior Cruciate Ligament Reconstruction**

PHASE I (weeks 1 to 2)	PHASE II (weeks 2 to 6)	PHASE III (weeks 6 to 12)
• Crutches WBAT—brace may be unlocked for gait training after 1st week. Brace locked in extension, unlocked after 1st week • Cryotherapy, compression, and elevation to control pain and swelling • Passive and active-assisted ROM with emphasis on regaining full passive extension • Calf and hamstrings stretching • Quad sets and SLR • Gentle patellar mobilization (grade 1–2) • High-intensity electrical stimulation for quadriceps—10 s on/50 s off for 10 min once per day • Weight-shifting exercises	• Crutches WBAT, discontinue when symmetrical extension, no quadriceps lag, 120° flexion and normal gait • Brace is unlocked and continued until 120° flexion • Cryotherapy to control pain and swelling • Continue passive and active-assisted ROM • Continue calf and hamstring stretches • Continue quad sets and SLR—add resistance for SLR as tolerated • Progress weight-shifting exercises to unilateral balance exercise • Continue patellar mobilization as necessary to restore normal patellar mobility—emphasis is on normal superior glide to permit full active extension without a quadriceps lag • Continue high intensity electrical stimulation • Biofeedback training if difficulty initiating and maintaining a quad set • OKC knee extension from 90°–60° with light resistance (ankle weights) • OKC knee flexion from 0° to 90° with light resistance (ankle weights) • Weight-bearing CKC exercises from 0° to 45°—begin with weight equally distributed on each leg and progress to unilateral exercise as tolerated (mini-squats, wall slides, step-ups) • Pool therapy for ROM and gait training	• Crutches are discontinued • Brace is discontinued • If ROM goals are not met, additional physical therapy interventions may be necessary, such as cyclic or static stretching, joint mobilization, and serial casting or splinting • When the patient achieves full extension, 90° to 100° flexion, SLR without lag, no pain or swelling and normal gait, the intensity and frequency of physical therapy is increased to 2–3 times/wk • Continue passive and active-assisted ROM • Continue calf and hamstring stretches • Continue patellar mobilization • Progressive resisted OKC knee extension from 90° to 45° (progress to weight machine as tolerated) • Progressive resisted OKC knee flexion from 0° to 90° (progress to weight machine as tolerated) • Progressive resisted hip exercises • Progressive resisted unilateral weight-bearing CKC exercises from 0° to 60° (e.g., leg press, squats, lunges) • Balance and perturbation training exercises • Low-level plymometrics (e.g., step and land, bilateral low-level box drops) • Walking-based agility exercises • Low impact aerobic training (e.g., ergometer, elliptical, treadmill) • Continue high intensity electrical stimulation

Table 32-5 IKDC Guidelines Using Differences in Range of Motion as Compared to the Contralateral (Uninjured) Knee.

IKDC Guidelines	Extension	Flexion
Normal	<2°	<5°
Nearly Normal	3-5°	6-15°
Abnormal	6-10°	16-25°
Severely Abnormal	>10°	>25°

Techniques for Progressive Increase in Range of Motion

- Measure ROM using a goniometer and interpret according to IKDC guidelines (Table 32-5).

Manual Therapy Techniques

- Patellar mobilization in the directions of medial/lateral and superior/inferior glide should be performed to patella to prevent loss of patellar mobility, which can predispose to quadriceps inhibition, and arthrofibrosis.

Soft Tissue Techniques

- Wound care for incisions.
- Suture removal 1 week after surgery.

Stretching and Flexibility Techniques for the Musculotendinous Unit

Extension

- Hamstring and gastrocnemius stretches should be initiated immediately after surgery
- Full passive extension symmetrical to the noninvolved knee should be achieved by the first or second postoperative week.
- A safe, prolonged stretch into extension can be achieved by performing the "prone hangs" without (Figure 32-41*A*) or with a light weight (Figure 32-41*B*), or "heel props" (Figure 32-41C).
- Passive knee extension involves relaxing the knee under its own weight with the heel propped and the knee unsupported such as resting the heel on another chair or stool while sitting.

Flexion

- Flexion is gradually increased after the first postoperative week.
- 90 to 100 degrees of knee flexion should be achieved within 2 to 3 weeks after surgery (unless concomitant meniscus repair in which case knee flexion is limited to 90 degrees for 4 to 6 weeks after surgery).

TIMELINE 32-6: **Postoperative Rehabilitation After Anatomic Anterior Cruciate Ligament Reconstruction** (Continued)

PHASE IV (weeks 12 to 20)	PHASE V (weeks 20 to 32)	Phase VI (weeks weeks 32 to 52)
• Depending on progression, insurance and desired level of activity, physical therapy is continued • Home exercise program for continued strengthening • Gradually progress to functional re-training and conditioning program • Frequency of physical therapy can be decreased to 1–2 times/mo to monitor and progress the program • Progression of activity is dependent on absence of pain, swelling and instability, recovery of quadriceps strength, progression of physical activities, and physician clearance • Stretching exercises of hamstrings, calf, quad, iliopsoas, tensor fascia lata/IT band, and hip adductors • Full-arc, progressive, resisted OKC knee-extension exercises • Full-arc, progressive, resisted OKC knee-flexion exercises • Progressive resisted hip exercises • Quantify muscle strength regularly • Full-arc, progressive, resisted unilateral weight-bearing CKC exercises (e.g., leg press, squats, lunges) • Advanced balance and perturbation training exercises (e.g., random, larger destabilizing loads) • Start pool therapy for preparation to return to running and jumping • Gradually progress to in-line jogging (no jumping or cutting)	• Depending on the quad index, activity can be progressed. When symmetrical muscle bulk is achieved, use of a functional brace is recommended • Continue muscle stretching • Continue muscle strengthening (OKC/CKC) while increasing resistance • Gradually advance balance and perturbation training exercises to plyometric exercises. Depending on quad index advance to single-leg activities • Start submaximal agility exercises and gradually progress to sprinting and cutting drills, depending on the quad index	• Use of a functional brace is recommended for at least the duration of the first full season • Continue muscle strengthening (OKC/CKC), but decrease frequency to 1 to 2 times per week for maintenance when symmetrical strength is achieved • Make plyometric exercises more challenging and emphasize correct movement patterns • Progress agility drills to sport specific training activities • Gradual return to practice, starting with unopposed drills, progressing to opposed drills followed by return to competition

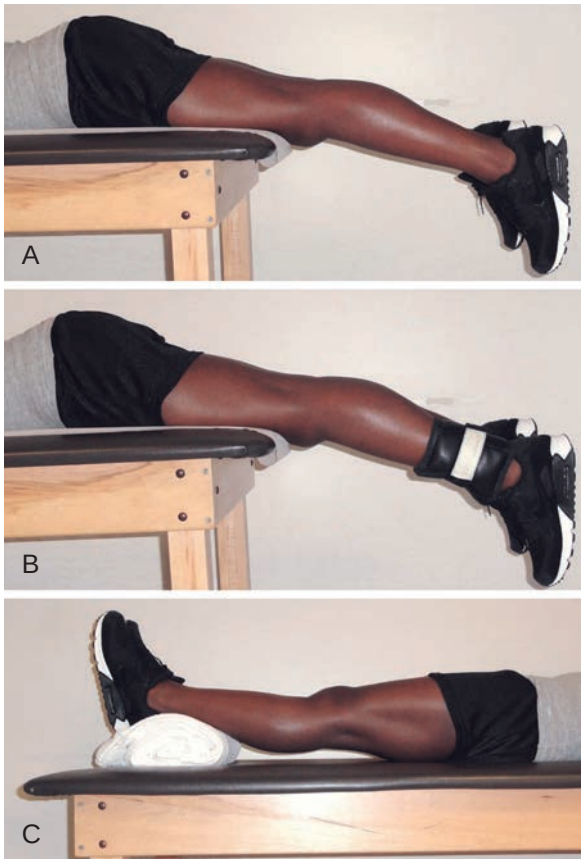

FIGURE 32-41. Prone hang exercise without (**A**) and with (**B**) a light ankle weight. Note that the knee is off the edge of the table. (**C**) Heel prop exercise using a rolled towel.

- Increase in knee flexion can be achieved through the initiation of heel slides (Figure 32-42) and passive, active-assisted, and or active knee flexion exercises (Figures 32-43 and 32-44) immediately after surgery.

ROM

- Continuous passive motion (CPM) may be considered to increase ROM.

Other Therapeutic Exercises

- Side-lying straight leg raises (Figure 32-45) may be performed to increase strength of the gluteus medius. When performing side-lying hip abduction, the hip should be slightly extended and externally rotated to facilitate activation of the gluteus medius.
- Prone hip extension may be performed to increase strength of the gluteus maximus and hamstrings.
- Side-lying hip adduction may also be performed, however if concomitant MCL repair was performed, hip adduction exercises should be deferred for 4 to 6 weeks to avoid premature valgus stress on the healing MCL.
- Standing heel raises with the weight equally distributed on both legs may be performed to provide exercise for the calf muscles. Resistance is limited to body weight only at this point in the rehabilitation process.

FIGURE 32-43. Wall slides. The patient is instructed to allow the operative knee to gently slide down the wall by bending the knee. The nonoperative leg can be used to apply an additional downward force (as shown).

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Quad sets and straight leg raises are used to regain control of the quadriceps muscle.
- Based on the current best evidence high intensity neuromuscular electrical stimulation (NMES) for the quadriceps should be used for all patients starting within the first week after surgery.[6,13] When performing high intensity NMES, the electrically elicited

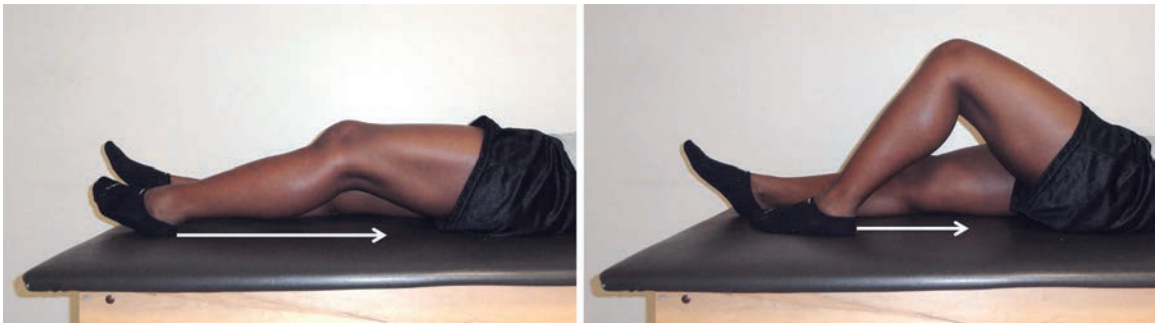

FIGURE 32-42. Heel slides. Heel is pulled towards the buttocks cycling in as full ROM as tolerated.

FIGURE 32-44. Beginning with the operative leg resting on top of the nonoperative leg in full extension, the patient is instructed to gradually allow the injured leg to fall into flexion. When the operative leg is maximally flexed (depending on the patient's comfort), the nonoperative leg is placed on top of the operative leg to apply a gentle force into further flexion.

contraction should be a sustained tetanic contraction of sufficient intensity to cause the patella to migrate superiorly.

- Prone isometric hamstring exercises with the knee in 30° to 45° of flexion may be performed for patients that underwent reconstruction with an allograft or bone–patellar tendon-bone autograft. For patients that underwent harvest of a hamstring graft or for those that had a meniscus repair, isometric hamstring exercises are avoided for the first 4 to 6 weeks to allow for soft tissue healing.
- If patients have difficulty regaining quadriceps control, as evidenced by the inability to perform an isolated quadriceps contraction, biofeedback training should be considered.

FIGURE 32-45. Straight leg raise. (**A**) Prone straight leg raise. (**B**) Seated straight leg raise.

Open and Closed Kinetic Chain Exercises

- Open kinetic chain exercises with resistance for the quadriceps and hamstrings are not indicated within the first 2 weeks of surgery.
- The patient may perform a simulated leg press from 60° to 0° against light elastic tubing in the seated position.
- Standing weight shifts, in which the patient shifts his or her weight to the surgical leg may be performed. Initially the patient should be encouraged to bear 50% body weight on the surgical leg. Gradually, the amount of body weight that can be borne by the surgical leg is increased until the patient can bear full body weight and maintain balance during single leg stance. When performing the weight shifts, the patient should keep the knee in extension, but not hyperextension, and the patient should also perform a standing quad set when shifting weight to the surgical knee. Care should be taken to avoid an instability episode of the surgically reconstructed knee.

Techniques to Increase Muscle Strength, Power, and Endurance

- Emphasis during the first 2 weeks after surgery is on regaining motor control, not on increasing muscle strength, power, and endurance.

Neuromuscular Dynamic Stability Exercises

- Neuromuscular dynamic stability exercises during the first 2 weeks after surgery are limited to regaining control of the muscles crossing the knee, straight leg raises for improved hip muscle function, and weight shifts in standing.
- Limited trunk and core stabilization exercises with an emphasis on the abdominal muscles (Figure 32-46) can be performed at this time.

FIGURE 32-46. Abdominal hold exercise for balance, core muscle stabilization, and lumbopelvic muscle strengthening.

Milestones for Progression to the Next Phase

- Minimal pain and swelling of the knee
- Full passive extension symmetrical to the noninvolved knee
- Ability to perform an isolated contraction of the quadriceps that results in full broadening of the muscle and superior migration of the patella
- Ability to perform a straight leg raise without a quadriceps lag
- 90° to 100° of knee flexion.

Phase II (weeks 2 to 6 postoperatively)

Clinical Pearl

During the early phases of rehabilitation, graft strength is suboptimal. Attention should focus on restoring ROM and improving muscle strength[14]. During this phase of rehabilitation, quadriceps and hamstring strength can be maximized without endangering the graft by utilizing isometric and limited arc progressive resistance exercises. Inadequate progression of ROM, especially with regards to extension, should be treated aggressively.

Goals

- Protect the healing structures.
- Reverse the effects of immobilization and restore ROM.
- Further develop muscle control and strengthening.
- Restore normal gait pattern and increase tolerance for ambulation.

Protection

- The brace is continued until the patient has comfortably achieved 120° of knee flexion.
- Weight bearing as tolerated (WBAT) with crutches assistance is continued until the following criteria are met:
  - Minimal pain and swelling
  - Full passive knee extension symmetrical to the noninvolved knee (measure ROM and use IKDC score in Table 32-5).
  - At least 100° to 120° of knee flexion.
  - Able to perform a straight leg raise without an extensor lag.
  - Normal gait pattern when walking without crutches.

Management of Pain and Swelling

- Cryotherapy, compression, and elevation should be continued to control pain, swelling, and inflammation. Persistent pain, swelling, and inflammation may result in decreased ROM, decreased quadriceps control, altered gait pattern, and a prolonged rehabilitation process.
- Transition to oral antiinflammatory medication is encouraged.
- Cryotherapy is recommended after exercise to control pain, swelling, and inflammation

Techniques for Progressive Increase in Range of Motion

- Measure ROM (using a goniometer) and interpret findings according to IKDC guidelines.

Manual Therapy Techniques

- Mobilization of the patella is continued to restore normal patellar mobility and to prevent arthrofibrosis.

Soft Tissue Techniques

- Scar mobilization of postsurgical incisions once closed.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Restore full extension symmetrical to the noninvolved side:
  - Continue hamstring and calf stretching.
  - Continue with passive knee extension including prone hangs and sitting with the heel propped and knee supported.
  - Passive manual stretching to increase knee extension may be used as necessary.
- Continue to gradually increase knee flexion to within 10° of the contralateral side by 6 weeks. If a meniscus repair was performed, ROM beyond 90° is permitted after 4 to 6 weeks and flexion and should be within 10° of the contralateral side 8 to 10 weeks after surgery. Activities to increase flexion include:
  - Active and active-assisted ROM—heel slides, wall slides (see Figure 32-42)
  - Manual and self-administered stretching
  - Riding stationary bike with seat adjusted to require increasing knee flexion. Resistance when pedaling stationary bike should be minimal at this time to avoid increased swelling and inflammation.
- Once the postsurgical incisions are closed, pool exercises can also be used to improve ROM, strength and gait. For example performing ROM of the knee, walking, and simulating bicycle motion in the pool. No jogging, diving, or whip kicks in the pool at this time.

Other Therapeutic Exercises

- Continue 4-way leg raises for strengthening hip flexors, extensors, abductors, and adductors. Light resistance can be applied below the knee. However, following MCL or LCL/posterolateral corner reconstruction, the resistance should be applied above the knee for hip adduction and abduction respectively.
- Continue heel raises, progressing to single leg heel raises as tolerated.
- Continue trunk and core stabilization exercises as tolerated.
- Upper body weight training can be initiated provided all exercises are performed in the seated or recumbent position.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Continue quad sets and straight leg raises. Emphasis should be on performing an isolated quadriceps contraction with hamstring co-contraction. During contraction of the quadriceps with the knee in full extension, the patella should glide superiorly symmetric to the contralateral side. Resistance can be added at ankle for SLR once the patient can perform a SLR without a quadriceps lag.
- High intensity NMES for the quadriceps should be continued.
- Biofeedback should be used if the patient has difficulty initiating a quad set. The physician should be alerted if the patient has a persistent knee extensor lag beyond 3 to 4 weeks after surgery.

Sensorimotor Exercises

- Standing weight shifts can be transitioned to single leg balance as tolerated. Initially this should be performed on a stable surface with eyes open with the knee in extension, but not hyperextension. The pelvis should remain level, and the trunk should remain stable.
- Single leg balance can be progressed to standing balance on a flexed knee (30°).
- When the patient can balance on a single leg with minimal deviations, balance activities can be progressed to an unstable surface (foam mat) and be performed with the eyes closed.

Open and Closed Kinetic Chain Exercises

- Limited arc open chain knee extension from 90 to 60° of flexion in seated position may be started once the patient has 100° of knee flexion. Light resistance up to 10 lbs. can be applied to ankle. Once the patient can perform limited arc knee extension with 10 lbs., the exercise can be transitioned to a leg extension machine.
- Unless the patient had a meniscus repair or a hamstring graft was harvested, the patient can begin performing resisted knee flexion in the prone and standing position from 0° to 90° once they have achieved 100° to 120° of active knee flexion. Light weight can be applied at the ankle. The exercise can be transitioned to a leg curl machine, once the exercise can be performed with 10 lbs. If the patient had a meniscus repair or a hamstring graft was used, resisted exercise for the hamstring is delayed until 6 to 8 weeks to permit sufficient soft tissue healing.

FIGURE 32-47. Mini-squats using a table for stabilization.

- Weight-bearing closed kinetic chain exercises; in the form of mini-squats (Figure 32-47) and wall slides may be performed in the range from 0° to 60° of flexion. Weight should be equally distributed on each leg. Weight-bearing CKC should be delayed until 6 to 8 weeks if there as a concomitant articular cartilage procedure performed.
- Leg press, using both legs simultaneously can be initiated with light resistance (less than body weight).
- Single leg CKC exercises in the form of single leg mini-squats and step ups/downs to and from a low height (3 inches) may be initiated if the patient demonstrates the ability to balance on a flexed knee with minimal hip or postural sway. During this phase, single leg CKC should be limited to 0° to 45° of knee flexion.

Techniques to Increase Muscle Strength, Power, and Endurance

- Progressive resistance exercises as described above are used to initiate muscle strengthening. Three to five sets of 8 to 12 repetitions are performed using resistance that is perceived to be light to moderate by the patient.
- Pedaling a stationary ergometer with low resistance can be initiated to improve cardiovascular endurance once the patient can comfortably pedal the bike freely without pain, stiffness, or swelling.
- Pain and swelling must be carefully monitored during this phase to avoid an increased or sustained inflammatory response of the knee.

Neuromuscular Dynamic Stability Exercises

- Neuromuscular dynamic stability training is essential for functional recovery following ACL reconstruction and secondary prevention (re-rupture or graft or contralateral ACL tear).
- During this period of time, neuromuscular dynamic stability training is limited to the hip, core, balance, and CKC exercises described above.

Functional Exercises

- Gait-training is performed to ensure that the individual uses a normal heel-toe gait and does not walk with a flexed knee during the mid-stance phase of gait.

Sport-Specific Exercises

- Sport-specific exercises are not encouraged during this phase of rehabilitation.
- Patients should be educated concerning their rehabilitation program and the expected time frame and requirements for return to activity.
- Careful adherence to the rehabilitation protocol and timely progression is necessary to allow for graft healing, especially for allograft ACL reconstruction.

Milestones for Progression to the Next Phase

- Minimal pain and swelling
- Full passive knee extension symmetrical to the contralateral knee and the ability to perform a SLR without a lag.
- 120° of knee flexion.
- Ability to walk without assistive devices or gait deviations.

If the patient is progressing well without complications (infection, signs and symptoms of instability or failed reconstruction, or intractable pain and swelling), he or she may progress to the next rehabilitation phase.

Phase III (weeks 6 to 12 postoperatively)

Clinical Pearl

The focus of Phase III rehabilitation is on increasing quadriceps strength and increasing tolerance for walking with a normal gait. Limited arc OKC and CKC quadriceps exercises with moderate to heavy resistance are used to increase quadriceps strength. To achieve normal gait, focus should be placed on achieving full extension at heel strike and at the end of the midstance phase. A "bent knee gait" that persists throughout midstance should be closely examined and treated. The ability to maintain a normal gait during sustained walking is emphasized.

Goals

- Continue to protect the healing structures.
- Restore full ROM symmetrical to the contralateral knee.
- Progress strength training for all key muscle groups in both lower extremities.
- Increase tolerance for walking.
- Increase cardiovascular endurance.
- Continue to progress hip and core muscle strengthening, balance, and development of neuromuscular dynamic stability.

Protection

- Use of crutches and rehabilitation brace have been discontinued.
- Functional brace is not used for rehabilitation activities during this phase of rehabilitation.

Management of Pain and Swelling

- Pain and swelling should be minimal. If present, continue oral analgesics as needed.
- Cryotherapy should be used after exercise to minimize pain and swelling associated with activity induced inflammation.
- Pain and swelling during rehabilitation exercises should guide the rehabilitation progression. If pain and swelling persist or increase, the pace and intensity of the rehabilitation program should be reduced.
- The soreness rules described by Lynch et al. are helpful to guide progression of the rehabilitation program.[15]
- Persistent, moderate to severe pain, and swelling should be brought to the attention of the referring surgeon.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Patellar mobilization may be used as needed to address hypomobility or complaints of patellofemoral pain
- Tibiofemoral joint mobilization may be used as needed to restore full ROM of the knee.

Soft Tissue Techniques

- Scar mobilization of incisions may be continued as needed.

Stretching/Flexibility Techniques for the Musculotendinous Unit

- Stretching for the hamstrings and calf muscles is continued.
- Stretching for the rectus femoris, iliotibial band, hip flexors, and hip adductors is initiated as indicated based on assessment of length of these muscle groups.
- Mobilization and passive stretching of the joint is used as indicated to restore full passive extension and flexion of the knee. Stretching to restore full joint motion may make use or prolonged low-load or repeated cyclic stretch as tolerated by the patient.

Other Therapeutic Exercises

- Hip and lumbopelvic stabilization exercises are continued to improve motion control of the lower extremity during functional activities. Emphasis is on developing muscles to prevent excessive hip adduction and internal rotation and trunk sway and lean.
- Four-way hip exercises in the recumbent position may be replaced with four-way hip exercises in standing with the use of elastic bands for resistance.
- Side steps and diagonal walking with elastic bands for resistance can be used for further strengthening of the

hip. Core and balance exercises should include activities that focus on strengthening the internal and external obliques, recuts abdominus, transverse abdominus, multifidus and erector spinae muscles, and paraspinal musculature.
- Core stabilization exercises, such as plank or Navy Seal holds, pelvic tilts, bridging, and lateral side support, have been used in injury prevention programs and should be incorporated in postoperative rehabilitation.
- Single-leg heel raises and double-limb heel raises with added external resistance are performed for continued strengthening of the calf muscles.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Full activation of the quadriceps as evidenced by the ability to perform a straight leg raise without a knee extensor lag should have been achieved before entering this phase of rehabilitation.
- Neuromuscular electrical stimulation (NMES) should be continued to further increase quadriceps muscle strength.

Sensorimotor Exercises

- Advance balance training by increasing the degree of task variability with less frequent verbal feedback or position cues.
- Additional activities, such as throwing and catching objects while balancing on one leg, will increase in task difficulty.
- Single-leg balance activities may be gradually increased in difficulty. For instance, through the addition of foam surfaces or a tilt-board introduces surface variability.
- Perturbations during balance exercises on a tilt and/or roller board have been shown to be beneficial for nonoperative treatment of ACL injuries.[16] As such, we recommend inclusion of perturbation training in rehabilitation following ACL reconstruction. Perturbation training should be initiated once the patient demonstrates mastery of balance activities on a tilt board or other unstable surface. Initially, perturbations should be done in a regular manner so that the patient is aware of the impending perturbation. Over time, the randomness and magnitude of the perturbation can be increased.
- These advanced balance techniques can be used during performance of activity related tasks to enhance the transfer of learned protective responses to actual functional performance situations.

Clinical Pearl

An ACL deficient knee suffers a loss of proprioception. Thus, neuromuscular balance training is critical for full functional recovery following ACL reconstruction. Furthermore, neuromuscular training in addition to bilateral strength training may aid in the prevention of graft re-rupture and contralateral ACL injury.[17,18]

Open and Closed Kinetic Chain Exercises

- Limited arc knee extension from 90° to 60° progressing to 90° to 45° on a leg extension machine should be continued for quadriceps strengthening.
- Resisted knee flexion exercises on a leg curl machine should be continued for hamstring strengthening.
- CKC exercises on both legs with weight evenly distributed on each leg was as well as single leg CKC chain exercises should be continued in the range from 0° to 60° progressing to 0° to 75° of knee flexion. Exercises may include step-ups/step-downs, leg press, squats, and lunges.
- During this phase, OKC and CKC must be done in a manner to protect the healing graft as well as to prevent the development of patellofemoral pain.

Techniques to Increase Muscle Strength, Power, and Endurance

- Moderate to heavy resistance should be used for 3 to 5 sets of 8 to 12 repetitions every other day (3 to 4 days per week) to ensure continued gains in strength. Resistance must be progressed to ensure continued strengthening as tolerated by the knee.
- Low-impact aerobic training activities should be performed for 30 minutes 3 times per week at an intensity sufficient to produce a cardiovascular training effect (60% to 80% maximum heart rate reserve). Aerobic training activities may include fast walking on treadmill, stationary ergometer, elliptical trainer, step machine, swimming (flutter kick only), and/or jogging in a pool.
- The soreness rules should be observed to prevent over training and an increased or persistent inflammatory response.

Neuromuscular Dynamic Stability Exercises

- Treatment techniques should be designed to allow for the development of individualized compensatory neuromuscular responses to potentially destabilizing loads on the knee.
- Gradually progress weight-bearing balance exercises from static to dynamic balance training.
- Doing so will prepare patients for plyometric exercises, agility training, and sport-specific exercises utilized in advanced phases of rehabilitation.

Functional Exercises

- Achieving normal gait and increasing tolerance for weight-bearing activities is a priority.
- While walking, the patient should focus on achieving full extension at heel strike and at the end of the midstance phase of gait.
- Gait training is helpful in the presence of an abnormal gait pattern despite full passive and active knee extension with adequate quadriceps strength.
  - Gait training on a flat surface focuses on the achieving a normal gait pattern by separating the walking movement into 3 phases: loading (or contact phase), midstance, and propulsion.

- In the loading phase, the knee should be extended at heel strike and then should flex slightly until the foot is loaded on the ground. During midstance, the knee should re-extend so that it is fully extended at heel off. After heel off, the knee should flex in preparation for the swing phase of gait.

Clinical Pearl

A "bent knee gait" is the lack of full knee extension at heel strike and/or the inability to achieve full knee extension at the end of midstance. A patient exhibiting this type of gait should be examined closely. Likely causes include a lack of passive extension, inadequate active knee extension, quadriceps muscle weakness, a motor control issue, pain, arthrofibrosis, or apprehension.

Milestones for Progression to the Next Phase

- Minimal pain and swelling.
- Passive and active extension of the operative knee should be symmetrical to the nonoperative knee.
- Flexion of the operative knee should be within 10o to15 o of the nonoperative knee.
- Adequate progression in neuromuscular balance training exercises.
- Tolerance for low impact aerobic activities.

Phase IV (weeks 12 to 20, or 3 to 5 months postoperatively)

Goals

- Restore full ROM of the knee symmetrical to the noninvolved side
- Continued improvement of strength with at least 70% quadriceps strength prior to initiation of running
- Continued improvement in neuromuscular control.
- Gradual increase in functional activity towards light in-line running.

Protection

- Functional brace is not used for rehabilitation activities during this phase of rehabilitation.

Management of Pain and Swelling

- Pain and swelling should be minimal and not hamper further rehabilitation.
- Cryotherapy after activity is recommended to control signs of inflammation.
- Soreness rules are followed to avoid increased or persistent inflammation.

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Stretching for the hamstrings, calf, rectus femoris, ITB, and hip flexors and adductors is continued as indicated based on assessment of musculotendinous length.
- Obtaining and maintaining full knee joint ROM remains important. Manual and self-administered stretching exercises as described above are continued if full ROM is not yet achieved.

Other Therapeutic Exercises

- Core, hip and lower leg muscle strengthening as described above is continued and advanced as tolerated.

Clinical Pearl

Anatomically placed grafts are exposed to increased loads compared to grafts that are placed nonanatomically.[19,20] Though the tensile strength of the graft is gradually improving throughout the phases of rehabilitation, care must be taken to avoid overloading the graft when rehabilitating patients after anatomic ACL reconstruction.

Sensorimotor Exercises

- Continue to advance balance training activities by increasing the degree of difficulty through reduced visual input, decreased surface stability and increased attention to other activities (catching/throwing a ball) while performing balance activities. Continue perturbation training with the use of tilt and roller boards. Perturbations should be larger and more random to allow the patient to develop strategies to adapt to potentially destabilizing loads.

Clinical Pearl

Perturbation training techniques (as used in the nonoperative ACL injury population) include the use of platforms and tilt-boards with application of controlled perturbation forces (Figure 32-48). In these techniques, the patient stands on the support surface on the involved limb and potentially destabilizing loads are applied to the knee through the roller board or tilt board. The load should be applied in a random manner without warning the patient. This will ensure the patient makes a quick, automatic response to the destabilizing loads. These techniques can also be used during the performance of activity related tasks, which may enhance carryover of learned protective responses to functional performance situations.[21]

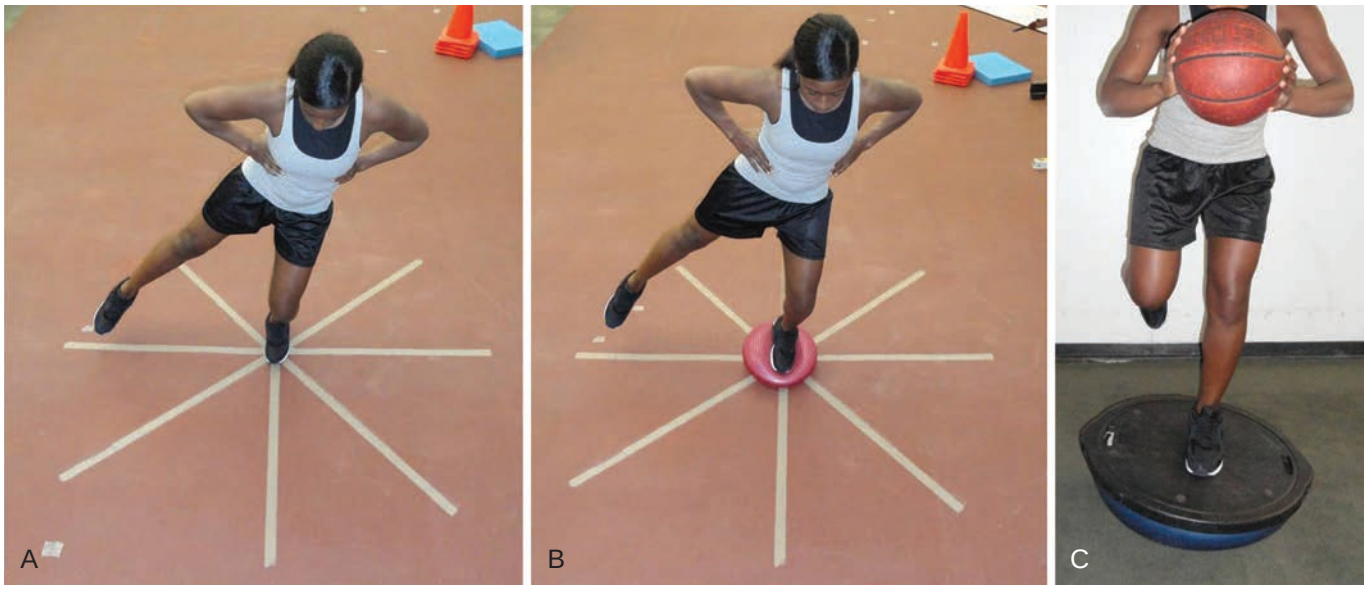

FIGURE 32-48. Perturbation exercises. (**A**) Single-leg outward reach drill requiring core stabilization and operative extremity strength. (**B**) Single-leg outward reach with surface variation (disc shown here). (**C**) Single-leg balance exercise on a balance ball while catching and passing a medicine ball or basketball (a sport-specific task).

Open and Closed Kinetic Chain Exercises

- OKC and CKC strengthening exercises should be continued and advanced as tolerated for further strengthening of the quadriceps and hamstrings.
- The range of OKC knee extension may be increased from 90° to 60° to 90° to 45° as tolerated by the patellofemoral joint.
- The range for CKC exercises may be increased from 0° to 60° to 0° to 90° as tolerated by the patellofemoral joint.
- More advanced CKC exercises include single leg press, single leg partial squats, and higher level step-up/step-down activities.
- Progressing from double- to single-leg extension activities will aid in avoiding compensation using the uninvolved extremity (Figure 32-49).
- Despite the fact that the tensile strength of the graft is increasing during this phase of rehabilitation, anatomic ACL reconstruction leads to increased loading of the graft.[19] Therefore, caution and prudence must be used in progressing the strengthening and functional training activities during this phase of rehabilitation.

Techniques to Increase Muscle Strength, Power, and Endurance

- Emphasis is on progressively increasing resistance with strength-training exercises.
- Generally 4 to 5 sets of 8 to 12 repetitions are performed with moderate to heavy resistance. Daily adjustable progressive resistance exercise program is used to progressively adjust working weight for resistance exercises. If greater than 12 repetitions can be

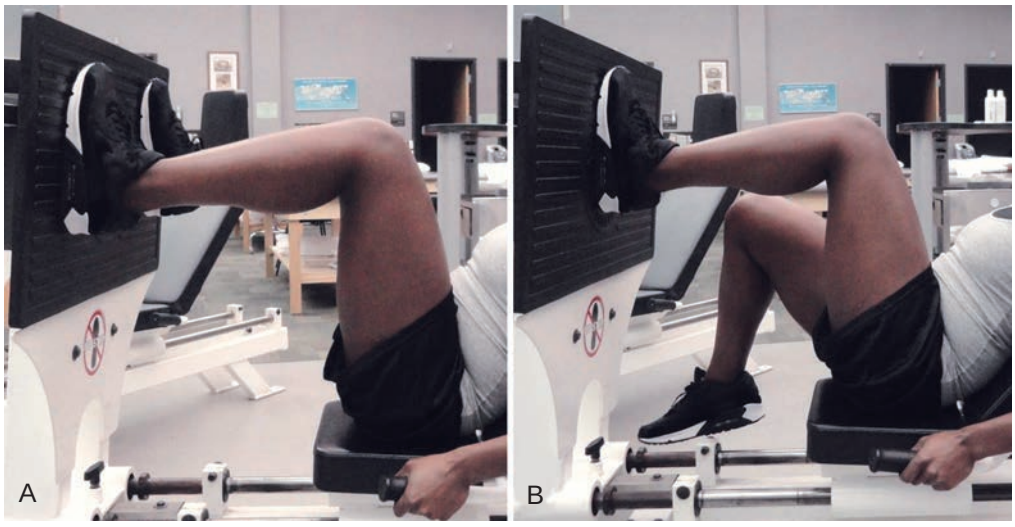

FIGURE 32-49. A, Double-leg press and **B,** single-leg press.

completed during third or fourth set, resistance for final set should be increased and new working weight for next training session should be established.
- Resistance exercises to increase strength are performed every other day, 3 days per week.
- Quadriceps strength should be assessed quantitatively. Options include isokinetic or isometric testing. If an isokinetic dynamometer is not available, a handheld dynamometer may be used. Use of a strap to stabilize the dynamometer and provide resistance may be necessary to ensure accurate use of the handheld dynamometer. If a dynamometer is not available, a 1- or 10-repetition maximum test may be used to assess strength.
  - The results of the quantitative strength test should be used to determine the quadriceps index, with this is the ratio strength of the involved knee to the uninvolved knee. Minimum quadriceps-index values required to progress to specific functional activities are as follows:
    - Running progression—70%
    - Agility training and jumping (both legs simultaneously)—85%
    - Hopping (single leg) and cutting—90%

Neuromuscular Dynamic Stability Exercises

- Continue to advance balance and perturbation training exercises as described above.
- Continue strengthening of hip and core trunk muscles as necessary to ensure good trunk and hip control during movement.

For all exercises, emphasize correct movement patterns. In particular, during weight-bearing exercises, ensure the patient performs the activity with good trunk and hip control. Provide cues as necessary to ensure that single leg weight-bearing exercises are performed with good technique and avoidance of excessive hip adduction and internal rotation as evidenced by medial collapse/valgus of the knee.

Functional Exercises

- In-line running on a treadmill or over the ground may be initiated if the patient's quadriceps index is at least 70%, and the patient can tolerate fast walking on a treadmill or over the ground for 15 minutes without gait deviations and signs of inflammation (pain, swelling).
- Running should begin at a slow, comfortable speed for short durations and distances. Alternating jogging and walking may be used as a transition to running.
- Running distance, time, and speed may be progressed as tolerated as long as there are no signs or symptoms of inflammation (pain, swelling) or gait deviations/asymmetries. A 10% to 15% increase in running volume per week is recommended.
- Running should only be straight ahead on a level surface. Avoid hills, inclement weather, and uneven surfaces.
- If increased joint pain (tibiofemoral or patellofemoral) or swelling or if asymmetry of gait develops, the jogging program should be reduced or eliminated, and the potential cause should be identified and addressed.

Clinical Pearl

Rehabilitation programs must be individualized to match each patient's needs. Next to the actual surgical procedure and the surgeon's preferences, individual factors play an increasing role in rehabilitation as time from surgery increases. Thus, the time frame for advancing to successive rehabilitation phases depends on individual progression. Initiation of higher-level functional activities (e.g., jumping, cutting, and pivoting) may differ by individual, sometimes deviating from the postoperative guidelines discussed.

Sport-specific Exercises

- As mentioned above, patients may begin in-line jogging with progression in speed and duration as tolerated.
- Jumping and cutting are not advised at this time.

Milestones for Progression to the Next Phase

- During this phase of rehabilitation, any residual deficits in ROM and flexibility should be resolved.
- Quadriceps strength should be 70% of the noninvolved knee as determined by isometric testing with a handheld dynamometer, on an isokinetic dynamometer in the isometric mode, or with a 1-repetition maximum quadriceps strength test.
- Ability to run for up to 2 miles without any pain or swelling or gait asymmetries.
- Surgeon's clearance should be obtained before advancing to the next phase.

Phase V (weeks 20 to 32, or 5 to 8 months postoperatively)

Clinical Pearls

More objective outcome measures are needed to assess a patient's readiness for return to sports. At this time, some institutions are using MRI to evaluate graft healing in conjunction with findings from the physical examination, the patient's subjective feelings of knee stability and the results of performance-based measures of function (single-leg hop tests, etc.). As described in a review by van Grinsven et al., current outcome measures used to inform the decision for return to sports include[21]:
- Visual Analog Scale (VAS) for pain
- Circumference measurement with a measuring tape to assess swelling and atrophy using comparison with the noninvolved leg used as a control.
- Goniometer to assess ROM.
- The International Knee Documentation Committee Subjective Knee Form can be used to assess symptoms and functional limitations.

- Hop tests to measure differences in total leg function between the involved and uninvolved knee. A minimum of 2 hop tests should be performed to increase sensitivity of detecting performance limitations.
- Quantitative Strength Testing to objectively measure strength of the knee stabilizers. This may include isokinetic testing, isometric testing with an isokinetic dynamometer, or handheld dynamometer, or determination of a 1- or 10-repetition maximum.

Goals

- No episodes of pain, swelling, and instability.
- Full ROM of the knee symmetrical to the noninvolved side
- Maximize strength, power and endurance. Achieve 90% quadriceps index.
- Optimize neuromuscular control.
- Begin agility, jumping (both legs), and hopping (single-leg) activities.

Protection

- A functional knee brace may be worn during functional training activities but is not required. Fitting of a functional knee brace is delayed until symmetrical thigh muscle bulk is achieved.

Management of Pain and Swelling

- Ice after activity is used to control pain and swelling if necessary.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Tibiofemoral and patellofemoral joint mobilization is used only if necessary to restore full ROM of the knee

Soft Tissue Techniques

- Only if necessary to restore normal mobility of the knee.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Stretching for the hamstrings, calf, rectus femoris, ITB, and hip flexors and adductors is continued as indicated based on assessment of musculotendinous length.
- Obtaining and maintaining full knee joint ROM remains important. Manual and self-administered stretching exercises as described above are continued if full ROM is not yet achieved.

Other Therapeutic Exercises

- Core, hip, and lower leg muscle strengthening as described above is continued and advanced as tolerated

Sensorimotor Exercises

- Continue advanced balance and perturbation exercises as described above.

Open and Closed Kinetic Chain Exercises

- OKC and CKC strengthening exercises are advanced as tolerated for further strengthening of the quadriceps and hamstrings.
- The range of OKC knee extension may be advanced to full range (90° to 0°) as tolerated by the patellofemoral joint.
- The range for CKC exercises may be increased from 0° to 90° as tolerated by the patellofemoral joint.
- More advanced CKC exercises include higher-level step-up/step-down activities, squats, and lunges.

Techniques to Increase Muscle Strength, Power, and Endurance

- Continued emphasis is on progressively increasing resistance with strength training exercises through full arc of motion as tolerated by patellofemoral joint using a daily adjustable progressive resistance exercise program 3 days per week.
- Quantitative quadriceps strength testing as described above should be continued. The minimum quadriceps index to initiate agility training and jumping (both legs simultaneously) is 85% and is 90% to initiate hopping (single leg) and cutting.

Neuromuscular Dynamic Stability Exercises

- Continue advanced balance and perturbation training exercises as described above.
- Continue strengthening of hip and core trunk muscles as necessary to ensure good trunk and hip control during movement.
- For all exercises, emphasize correct movement patterns. In particular, during weight-bearing exercises, ensure the patient performs the activity with good trunk and hip control. Provide cues as necessary to ensure that single-leg weight-bearing exercises are performed with good technique and avoidance of excessive hip adduction and internal rotation as evidenced by medial collapse/valgus of the knee.

Plyometrics

- Jumping and landing on both feet simultaneously may be started when the quadriceps index is greater than or equal to 85%, provided the patient can demonstrate good form with take-off and landing (no genu varum, hip adduction, or internal rotation during take-off and landing and weight forward on balls of feet and knees flexed when landing).
- Begin with single forward jumps taking-off and landing on both legs.
- When patient demonstrates good form and tolerance to forward jumps, patient can begin side to side jumping, jumping with rotation, and box jumps.
- As patient improves, he or she can progress from single jumps to consecutive jumps.
- Hopping on a single leg can be initiated when quadriceps index is greater than 90%, and the patient can

perform jumps on both legs with equal weight distribution and good form.
- Single-leg hopping follows same progression as jumping described above.
- Emphasize correct form including adequate knee flexion upon landing, no medial collapse of the knee (no hip adduction or internal rotation), and minimal trunk deviations.

Functional Exercises

- Submaximal agility drills may begin when the quadriceps index is greater than 85%, and the patient is tolerating running for 15 minutes with good form and the absence of symptoms.
- Agility drills include lateral shuffling, forward/backward shuttle runs, carioca, and ladder drills. Drills are initially performed submaximally at 50% effort and gradually progressed to 75% and 100% effort as tolerated by the patient.
- Ensure there are no compensation patterns when performing agility drills, particularly during deceleration phase.
- Cutting drills may be initiated when the quadriceps index is greater than or equal to 90%, and the patient is tolerating agility and jumping drills with without symptoms or compensation patterns.
  - Cutting drills begin with running "S" pattern
  - Progress to 45-degree cuts then to sharper cuts.
  - Pivoting and cut and spin drills should begin when patient is able to cut at sharp angles.
- Sprinting can begin when quadriceps index is greater than or equal to 90%.
  - Begin with transition from running to full sprint for short distances with gradual increase and decrease in speed to full spring.
  - Sprint distance progressed to 40 then 100 yards.

Sport-specific Exercises

- Sports-specific exercises include running, agility, jumping, hopping, and spring activities as described above.
- Return to practice is delayed until patient is able to perform full effort running, agility, jumping, hopping, and sprinting activities that are required for sport with good for without symptoms.

Milestones for Progression to the Next Phase

- No pain or swelling.
- Full ROM symmetrical to opposite knee.
- Quadriceps index greater than or equal to 90%
- Hop test scores greater than or equal to 90%. Hop tests include:
  - Single-leg hop for distance
  - Single-leg triple hop
  - Single-leg triple crossover hop
  - Timed 10-meter hop
- Tolerating full effort agility, jumping/hopping, cutting, and sprinting drills without symptoms or movement abnormalities.

Phase VI (weeks 32 to 52, or 8 to 12 months postoperatively)

Goals

- No pain or swelling.
- Full ROM symmetrical to contralateral knee.
- Quadriceps index equal to or greater than 90% of contralateral side.
- Hop test indices equal to or greater than 90% of contralateral side.
- Tolerating full effort agility, jumping/hopping, cutting, and sprinting drills without symptoms or movement abnormalities.
- Full participation in practice.
- Full return to prior level of sports activity.

Protection

- The patient can be fitted for a functional brace when thigh muscle girth is symmetrical (less than 1 cm side to side difference) to contralateral thigh.
- Functional brace is recommended for return to practice and games for at least first full season after surgery.

Techniques for Progressive Increase in Range of Motion

- Patient should have achieved full ROM by 3 months postoperatively.
- Manual therapy techniques as described in previous phases if full mobility is not yet achieved.
  Stretching/flexibility techniques for the musculotendinous unit as indicated by muscle length testing.
- Manual and self-administered stretching exercises as described above are continued if full ROM of the knee is not yet achieved.

Other Therapeutic Exercises

- Core, hip, and lower leg muscle strengthening as described above is continued and advanced as tolerated. Frequency may be decreased to once or twice per week for maintenance.

Sensorimotor Exercises

- Continue advanced balance and perturbation exercises as described above.

Open and Closed Kinetic Chain Exercises

- Continue full range OKC and CKC exercises to increase strength to increase or maintain strength to greater than or equal to the contralateral side. Once symmetrical strength is achieved, frequency may be decreased to 1 to 2 times per week for maintenance.

Techniques to Increase Muscle Strength, Power, and Endurance

- Continue with high-resistance strengthening exercises through full arc motion as tolerated by patellofemoral joint.

- Quantitative quadriceps strength testing as described above should be continued. Quadriceps index should be greater than or equal to 90%.
- Strength training may be decreased to 1 to 2 times per week for maintenance once 90% strength is achieved.

Neuromuscular Dynamic Stability Exercises

- Continue maintenance program of advanced balance and perturbation training exercises as well as continued strengthening of the hip and core trunk muscles to ensure good trunk and hip control and to minimize the risk of re-injury.
- Emphasize correct movement patterns for all exercises.

Plyometrics

- Jumping and hopping exercises should gradually be made more challenging by changing the height and/or distance of jumps and hops, speed of the drills, directions, and by combining multiple tasks.

Functional Exercises

- Continue agility, cutting, and sprinting drills.
- Incorporate drills within context of practice.
- Cutting and jumping drills should include anticipated and unanticipated movements.

Sport-specific Exercises

- Continue agility, jumping, hopping, cutting, and sprinting drills within context of practice.
- Practice should initially consist of unopposed drills followed by drills against opposition as player regains confidence and skill.
- Sport-specific activities may include:
  - Basketball: Almost all of sport-specific rehabilitation after 24 weeks should consist of plyometrics and agility drills.
  - Soccer: In the later stages of sport-specific rehabilitation, most of the drills should consist of cutting and progress to unanticipated cutting.
  - Football: Sports-specific rehabilitation drills are position-specific.
  - Softball: Practice swings at full speed and mimic sprinting down the first base line. Sport-specific rehabilitation defensive drills are infield or outfield specific.

Clinical Pearls

- Tendon graft healing takes place in 4 successive phases: initial necrosis, revascularization, cellular repopulation, and remodeling[22,23]. Revascularization ensures graft viability, which facilitates subsequent remodeling and increase in tensile strength[24]. If an athlete desires return to sports prior to 36 weeks, magnetic resonance imaging can be used to assess for graft healing[25-27]. Indications of a healing graft include increased water content of the graft, an indication of vascularity and graft tensile strength, and decreased graft signal intensity.
- Improved surgical techniques including anatomic placement of the ACL graft are associated with lower morbidity and improved recovery time. New surgical developments tend to make athletes desire earlier return to sports. For instance, following anatomic DB reconstruction using a quadriceps autograft, patients have been observed to advance to full range of motion with minimal pain and swelling and normal unassisted gait within 6 weeks postoperatively. Though the athlete may appear advanced clinically, the ACL graft may not be fully healed until months later. Thus, it is important for clinicians to emphasize careful and steady rehabilitation to prevent future injury by allowing adequate graft healing and remodeling.

Milestones for Progression to the Next Phase

- Completion of the full rehabilitation program.
- All rehabilitation goals of the previous phases have been met.
- Quadriceps index of at least 90%.
- Tolerance for sport-specific exercises.

Criteria for Return to Sport

General

- Achievement of passive and active extension symmetrical to the noninvolved knee.
- Flexion within 5 degrees of the noninvolved knee.
- Minimal pain and no increase in swelling with exercise.
- Quadriceps index greater than or equal to 90% of the contralateral knee.
- Hop test indices greater than or equal to 90% of contralateral knee.
- Tolerating full effort agility, jumping, hopping, cutting, and sprinting activities without asymmetries or symptoms.
- Full participation in practice.

Sport-specific

- Return-to-sports criteria varies based on the level and type of activity required for each individual sport (Box 32-2).
- Patients must achieve a quadriceps index of 90% or greater and satisfy the above criteria to progress to sports-specific tasks including cutting, jumping, and plyometric activities.
- Athletes who play highly competitive contact sports involving cutting and pivoting (football, soccer, basketball) must be able to withstand a series of sports-specific tests to ensure readiness for return to pre-injury levels of activity.
- Some athletes choose return to sports at a lower competitive level or return to a different sport with less

BOX 32-2 An Example of a Return to Sports Test[18]

- 10-repetition maximum single leg squat with external weight.
- Single broad jump, landing on one foot.
- Triple broad jump, landing on one foot.
- Single-leg forward hop.
- Single-leg crossover hop.
- Single-leg medial and lateral hop.
- Single-leg medial and lateral rotating hop.
- Single-leg vertical hop.
- Single-leg triple hop.
- Timed 6-meter hop.
- 10-yard lower extremity functional test.
- 10-yard pro-agility run.

functional demands. In such cases, rehabilitation requirements would be altered to meet the patients' functional needs and sports-specific demands.

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Strengthening surrounding musculature (quadriceps) should always be a priority following ACL injury.
- ROM exercises and global flexibility should progress until active and passive ROM matches that of the uninjured limb.
- Development and maintenance of hip and core trunk muscle strength should always be a priority following ACL reconstruction.

Exercises and Other Techniques for Prevention of Recurrent Injury

- Prevention of recurrent ipsilateral or contralateral knee injury requires continued strengthening of the quadriceps and hamstrings as well as the hip and core trunk muscles.
- Balance training, plyometric, and agility training exercises similar to those included in ACL prevention programs.
- A recent review conducted by Wright et al. demonstrated that the rate of contralateral ACL tear is double the risk of ACL graft rupture in the ipsilateral knee after 5 years of follow-up.[18] Thus, it is important to rehabilitate both knees following ACL surgery for bilateral strength and to establish dynamic neuromuscular control.

Evidence

Harner CD, Irrgang JJ, Paul J, et al: Loss of motion after anterior cruciate ligament reconstruction. *Am J Sports Med* 20:499–506, 1992.

Retrospective review and follow-up examinations on 244 patients (minimum follow-up of 1 year) to assess risk factors and outcomes of patients who developed loss of motion after arthroscopic ACL reconstruction. (Level III evidence)

Kartus J, Magnusson L, Stener S, et al: Complications following arthroscopic anterior cruciate ligament reconstruction. A 2- to 5-year follow-up of 604 patients with special emphasis on anterior knee pain. *Knee Surg Sports Traumatol Arthrosc* 7:2–8, 1999.

The aim of this study was to assess knee function after arthroscopic ACL reconstruction and to analyze complications impeding rehabilitation, additional surgery until the final follow-up, and residual patellofemoral pain and donor-site problems. One or more complications impeding rehabilitation were recorded in 184 of 604 patients (30.5%). The most common was an extension deficit (>5 degrees) in 81 patients (13.4%). Patients with a full range of motion and a minimal loss (< or = 4 cm^2) of anterior knee sensitivity had significantly ($p < 0.01$) less subjective anterior knee pain than patients who did not fulfill these criteria. (Level II evidence).

Kato Y, Ingham SJ, Kramer S, et al: Effect of tunnel position for anatomic single-bundle ACL reconstruction on knee biomechanics in a porcine model. *Knee Surgery, Sports Traumatol Arthrosc* 18:2–10, 2010.

Ten porcine knees used for five different reconstruction techniques: three different anatomic SB [AM-AM (antero-medial), PL–PL (postero-lateral), and MID–MID] (n = 5 for each group), conventional SB (PL–high AM) (n = 5), and anatomic double-bundle (DB) (n = 5). ATT and in situ forces tested with robotic/universal force–moment sensor testing system. In situ forces were higher in anatomic ACLR, provided best stability and more closely restored normal knee kinematics.

van Grinsven S, van Cingel RE, Holla CJ, et al: Evidence-based rehabilitation following anterior cruciate ligament reconstruction. *Knee Surg Sports Traumatol Arthrosc* 18:1128–1144, 2010.

Systematic review to develop an optimal evidence-based rehabilitation protocol to enable unambiguous, practical, and useful treatment after ACL reconstruction. Thirty-two rehabilitation programs, randomized clinical trials, and reviews were included. The results indicate that an accelerated protocol without postoperative bracing, in which reduction of pain, swelling, and inflammation, regaining range of motion, strength, and neuromuscular control are the most important aims, have important advantages, and do not lead to stability problems. (Level II evidence)

Wright RW, Magnussen RA, Dunn WR, et al: Ipsilateral graft and contralateral ACL rupture at five years or more following ACL reconstruction: A systematic review. *J Bone Joint Surg Am* 93:1159–1165, 2011.

Systematic review of Level I and Level II prospective studies evaluating the long-term rate of ACL graft rupture and ACL rupture in the contralateral knee, following primary reconstructions. After 5 years follow-up, the risk of ACL tear in the contralateral knee (11.8%) is nearly double the risk of ACL graft rupture in the ipsilateral knee (5.8%). (Level II evidence)

Yagi M, Wong EK, Kanamori A, et al: Biomechanical analysis of an anatomic anterior cruciate ligament reconstruction. *Am J Sports Med* 30:660–666, 2002.

Controlled laboratory involving 10 cadaveric knees subjected to external loading conditions. Anterior tibial translation for

double-bundle anatomic reconstructions was significantly closer to that of the intact knee than was the single-bundle reconstruction, suggesting that anatomic reconstruction may produce a better biomechanical outcome, especially during rotatory loads. (Level II evidence)

Multiple-Choice Questions

QUESTION 1. Which of the following exercises are focused on obtaining full extension in the immediate postoperative period (0 to 14 days)?

A. Multidirectional mobilization of the patella.
B. Active mobilization with "heel slides".
C. Aggressive manipulation through a range of motion identical to the contralateral knee.
D. Safe, prolonged stretching with a "prolonged hang" or "heel prop" exercises.

QUESTION 2. Crutches may be discontinued when the patient has reached which of the following rehabilitation milestones?

A. During the first postoperative week to encourage quadriceps strengthening.
B. Once a normal gait pattern is attained without extensor lag on straight leg raise.
C. Once 80 to 90 degrees of passive knee flexion has been obtained.
D. Not before a quadriceps index is >90%.

QUESTION 3. The beginning of in-line jogging may be initiated at:

A. Weeks 2 to 6, before hip and lumbopelvic stabilization.
B. Weeks 6 to 12, once the brace has been discontinued.
C. Weeks 12 to 20, if treadmill walking is tolerated with a quadriceps index of at least 70%.
D. Weeks 20 to 32, after the patient has demonstrated sufficient strength on consecutive hop tests.

QUESTION 4. Causes of a "bent knee gait" include all of the following EXCEPT:

A. Hamstring weakness.
B. Lack of passive extension.
C. Arthrofibrosis.
D. Postoperative pain.

QUESTION 5. Which of the following exercises focus on regaining balance proprioception?

A. Add variation in surface stability and vary visible input to agility training and sports-specific exercises.
B. Increase speed of in-line running by 10% to15% per week.
C. Addition of a functional brace at 36 weeks.
D. Closed kinetic chain exercises from 0 to 45 degrees of flexion.

Answer Key

QUESTION 1. Correct answer: **D** (see Phase I, Increase ROM)

QUESTION 2. Correct answer: **B** (see Phase II, Protection)

QUESTION 3. Correct answer: **C** (see Phase IV, Functional Exercise)

QUESTION 4. Correct answer: **A** (see Phase III, Clinical Pearls)

QUESTION 5. Correct answer: **A** (see Phase IV, Sensorimotor Exercises)

Chapter 33

Posterior Cruciate Ligament Injuries

INTRODUCTION

Robert F. LaPrade, MD, PhD, Casey M. Pierce, MD, and Scott A. Wilkins, DPT, OCS

Epidemiology

- Injuries to the posterior cruciate ligament (PCL) are rare compared with ACL injuries.
  - Comprise between 3% and 23% of knee injuries and usually occur in combination with other ligament injuries
  - Schulz et al. reported that 33% of PCL injuries are sports related.
  - These numbers are highly dependent on the patient population because PCL injuries are most frequently trauma associated rather than sports related.
  - The PCL has an intrinsic healing capacity not seen in the ACL, so chronic injuries can undergo some healing and can go undiagnosed for long periods of time.
- Low grade/minor tears can be asymptomatic.
  - NFL football player study found 2% of pre-draft players have PCL insufficiency.
- Isolated PCL injuries are less common and account for between 3% and 20% of PCL injuries.
  - PCL is stronger than the ACL in terms of tensile strength.

Age

- Mean age 27.5 ± 9.9 years[1]

Sex

- Almost 80% male likely because of a higher number of males active in contact/collision sports[1]

Sport

- Contact/collision sports, skiing, and soccer mostly but also football, hockey, and wrestling
  - 40% sports related

Position

- Soccer goalie, also players in football who get tackled (quarterback, running back, wide receiver)
- Mechanism of injury puts them at risk for the common flexed knee with anterior tibial blow mechanism

Pathophysiology

Intrinsic Factors

- Movement patterns that are common are falls on a flexed knee, which are commonly seen with cutting in football and planting for leverage in wrestling.
- Neuromuscular development, proper training, stretching, strengthening, and conditioning and proper technique when landing from a jump can contribute to preventing PCL injury.
- There is an increased risk seen with affected siblings, so there is a probable genetic component.
- Decreased risk with certain genetic mutations and polymorphisms in the COLIA1 gene
  - Specifically increased production of collagen type Iα 1 mRNA and proteins
    - Increases tensile strength of tendons
    - Also characteristic of fibrotic diseases and low bone mineral density (BMD)
- Increased risk with other polymorphisms of the COL1A1 that lead to increased risk of soft tissue rupture
- Age, flexibility, previous injury, overuse
- Unlike the ACL, the PCL has an intrinsic ability to heal and is stronger so it is less likely to be injured

Extrinsic Factors

- Footwear: With any sport footwear, it is critical to help prevent slipping and twisting injuries to the knees.

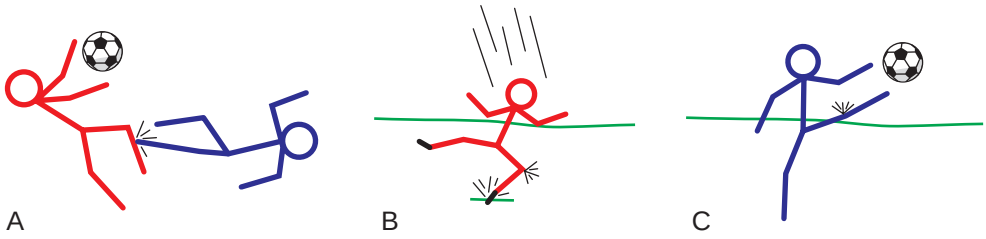

FIGURE 33-1. The three most common mechanisms of injury to the posterior cruciate ligament: direct anterior proximal tibial blow to a flexed knee (**A**), falling on a flexed knee with the foot plantarflexed (**B**), and sudden, powerful forced hyperextension (**C**).

- Environmental conditions that increase the likelihood of slipping or hyperextending the knee increase the risk of injury:
  - Wet or icy fields could contribute to this.
- Lifestyle
- Motor vehicle accidents are a common cause with the well-known "dashboard" injury (knee driven into dashboard on impact)
- Rigid structures on the playing field such as soccer, football, or hockey goal posts

Traumatic Factors

- Typical mechanism is a direct anterior proximal tibial blow to a flexed knee like a hockey goalie sliding into the goal post or soccer goalie sliding into another player (Figure 33-1*A*)
- Second most common is fall on the flexed knee with foot plantarflexed illustration (Figure 33-1*B*)
- Third most common is sudden, powerful forced hyperextension (Figure 33-1*C*)

Classic Pathological Findings

- Increased posterior translation on posterior stress x-rays (Figure 33-2)
- Increased posterior sag of the tibia
- Midsubstance ruptures
- Proximal or distal bony avulsions (Figure 33-3)
- On arthroscopy, the torn PCL may be visualized directly
  - In addition, the ACL appears slack when the PCL is torn; known as the "sloppy" or "slack" ACL sign (Figure 33-4*A*)
    - This is secondary to posterior tibial subluxation owing to the loss of support from a torn PCL and can be restored with an anterior translation force (Figure 33-4*B*)
    - The practitioner may also observe signs of damage secondary to the PCL injury such as altered tibial/femoral contact points, anterior horn meniscal tears, and degenerative changes

Clinical Presentation

History

- Typical history involves a direct blow to the anterior tibia with the knee flexed or a forced hyperextension
- Pain and swelling following the injury
  - Recurrent swelling or effusion
  - Less likely to complain of instability compared with ACL injuries
  - Instability with descending stairs, going down slopes or sudden decelerations, and also when on uneven ground.
  - Athletes may complain of generalized pain around the knee, and feel that "something is not right"

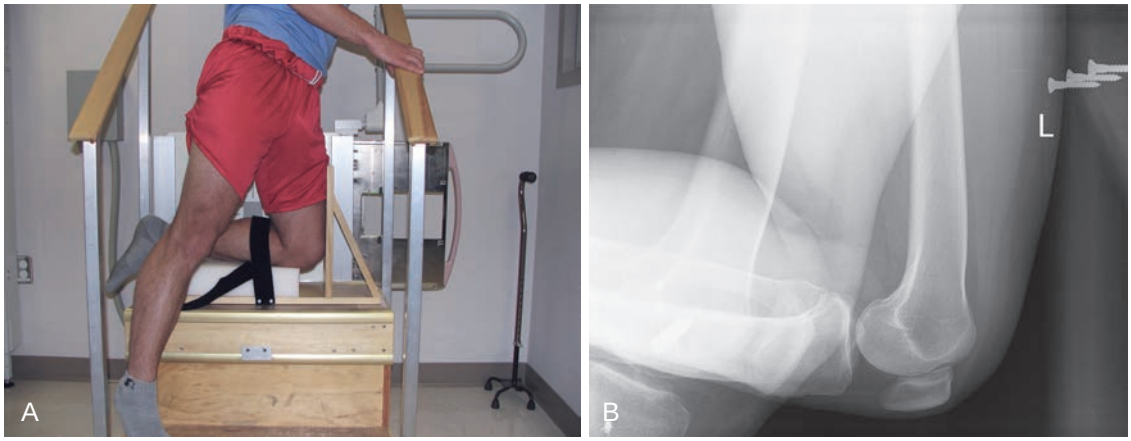

FIGURE 33-2. Posterior stress radiographs: setup (**A**) and an example radiograph (**B**).

FIGURE 33-3. Sagittal magnetic resonance image of a PCL tibial avulsion.

- Chronic injuries tend to complain of pain on walking for prolonged periods and when coming down stairs
- Low grade/minor tears can be relatively asymptomatic → football player study found 2% of pre-draft players have PCL insufficiency
- Torg et al. found that patients with isolated PCL injuries tend to remain asymptomatic compared to those who have combined injuries because of degenerative changes in the medial/lateral compartments.
- Patients may complain of numbness, tingling, or footdrop if they have a concurrent neurovascular injury.

Physical Examination

Abnormal Findings

- Gait pattern observation
  - Varus thrust gait could indicate a combined PCL/PLC (posterolateral corner) injury.
    - A varus thrust possibly combined with a hyperextended knee as the patient walks
  - An antalgic or quadriceps avoidance gait could indicate an ACL or combined ACL/PCL injury.
  - Studies have found quadriceps strength in chronic PCL-deficient patients to be compromised at higher knee flexion angles.
    - Patients tend to walk with a bent knee gait to avoid terminal hyperextension and external rotation of the tibia on the femur caused by posterior subluxation of the lateral tibial plateau.
- Classically mild joint effusion
- Misalignment of the limbs when standing and sitting with the knees flexed; important in chronic injuries
- Scars indicative of previous surgeries
- Palpation of the tibial plateau with the patient lying supine and having the knees flexed at 90°
  - Anterior border of the tibial plateau should sit 1 cm anterior to the medial femoral condyle
    - Grade I PCL injury → plateau still anterior
    - Grade II PCL injury → plateau now flush with medial condyle
    - Grade III PCL injury → plateau now posterior to condyle
- Sag test: Posterior sag of the subluxed tibia with patient's hips flexed to 45° and knees flexed to 90° while the legs are supported (Figure 33-5)
- Posterior sag disappears when quads flexed at 60° knee flexion and feet on table (quads active test)
- Posterior drawer test: Patient should be supine with the hips flexed to 45° and knees flexed to 90°, the examiner pushes the tibia backward (Figure 33-6)
  - Increased laxity will be observed with a PCL injury.
    - Increased posterior translation of the tibia under the femur
  - 3+ posterior drawer test should be considered a combined knee ligament injury until proved otherwise
- Positive posterior shift test: Flex the hip to near 90°, then extend the flexed knee; a posteriorly subluxated tibia will reduce, causing a clunk
- Positive reverse pivot shift test: Supine patient with knee flexed to 90°, externally rotate the foot, feel for the posteriorly subluxated lateral tibial plateau under the femoral condyle and observe for abrupt reduction of the tibia as the knee is extended (Figure 33-7)

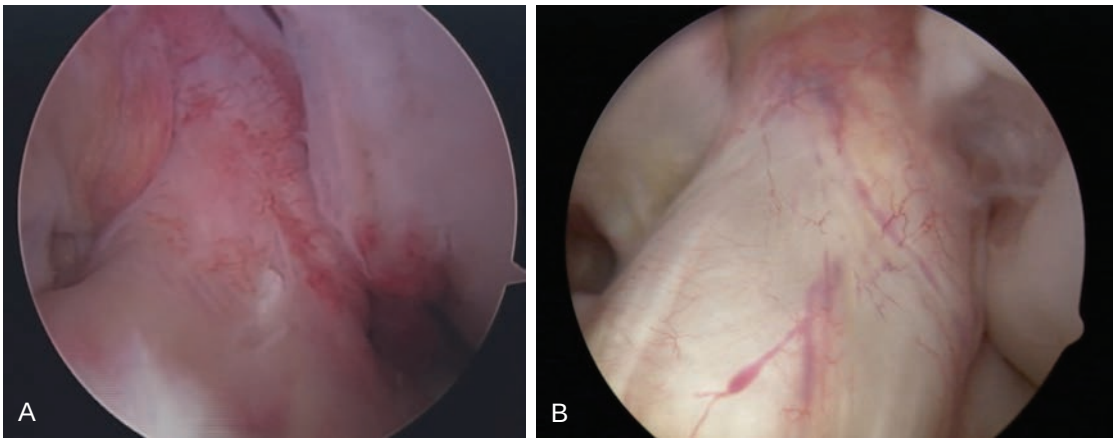

FIGURE 33-4. Arthroscopic PCL tear findings: ACL is "slack" or "sloppy" because of loss of support from the deficient PCL (**A**) and restored with an anterior translation force (**B**).

FIGURE 33-5. Sag test. Patient's hips flexed to 45° and knees flexed to 90° with the legs supported, the tibia will sag posteriorly with a PCL injury.

FIGURE 33-6. Posterior drawer test. Patient should be supine with the hips flexed to 45° and knees flexed to 90°.The examiner pushes the tibia backward. Increased laxity will be observed with a PCL injury.

FIGURE 33-7. Reverse pivot shift. Supine patient with knee flexed to 90°. Externally rotate the foot, feel for the posteriorly subluxated lateral tibial plateau under the femoral condyle, and observe for abrupt reduction of the tibia as the knee is extended.

- Caution: This can be positive in up to 35% of normal knees, so the examiner should check the normal contralateral knee.
- Positive dial test: Supine patient with knees at 90°, knees placed together and both feet externally rotated, positive if difference greater than or equal to 10° to 15° for combined PCL/PCL injury at 90° (Figure 33-8)
  - Repeat with patient prone and knees flexed at 30° and 90°
- Positive external rotation-recurvatum test: Patient supine, stabilize the thigh and lift the great toe, positive if increased recurvatum, varus, and external rotation (Figure 33-9)
  - Usually indicative of a combined posterolateral and ACL injury rather than an isolated PCL injury
- Inoue et al. found there were no difference in the electrical activity of the quadriceps and hamstrings in patients with chronic PCL deficiency compared with normal contralateral knee, but they did find earlier contraction of the gastrocnemius in PCL-deficient knees.
- Features of isolated PCL tears:
  - Abnormal posterior laxity (use less than 8 mm as a cutoff)
    - Laxity decreases with internal rotation of the tibia
  - Positive sag, quads active, and posterior drawer tests
- Features of combined PCL/posterolateral corner tears
  - Abnormal posterior laxity (cutoff is greater than 12 mm)
  - Positive recurvatum, reverse pivot shift, posterior shift, varus stress, posterolateral Lachman, pivot shift, posterolateral drawer, and/or dial tests
- Features of combined ACL/PCL tears
  - Positive Lachman and anterior/posterior drawer and pivot shift
  - Posterior tibial drop back beyond flat tibial step off (15–20 mm)
  - Increased varus/valgus laxity in full extension
  - Almost always found combined with posterolateral or posteromedial instability

Pertinent Normal Findings

- Isolated PCL injury
  - Negative/Normal tests: Valgus and varus stress, meniscus tear assessment, Lachman and posterolateral Lachman, pivot shift, posterolateral drawer, and dial test
- Normal anterior drawer and Lachman test (unless combined injury to ACL)
- No lateral/medial gapping, unless combined injury to PLC/MCL
- Often a negative meniscus assessment test
- Quadriceps and hamstring activity are normal in PCL-deficient knees
- No numbness or tingling which would indicate a more serious injury with a neurovascular injury

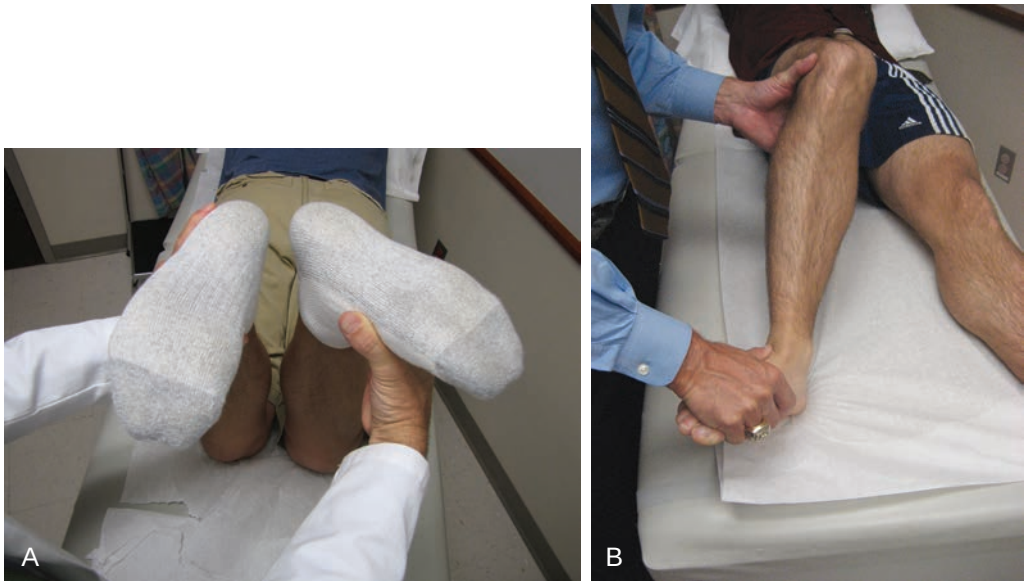

FIGURE 33-8. Dial test prone (**A**) and supine (**B**). Supine patient with knees at 90°, knees placed together and both feet externally rotated, positive if difference ≥10° to 15° for combined PCL/PCL injury at knees flexed to 90°.

Imaging

- Acute injury studies should include: AP, lateral and oblique radiographs, MRI, PCL stress radiographs
  - CT has little use unless the surgeon is trying to assess the size of an avulsion fracture for operative planning or suspects a tibial plateau fracture.
  - Posterior stress radiographs help demonstrate complete versus partial tears (see Figure 33-2)
    - Hewett et al.[2] studied normal knees and those with PCL injuries.
      - Normal knees have between 0 and 2 mm increased posterior translation
      - Partial tears 2 to 7 mm posterior translation
      - Complete tears 8 to 11 mm posterior translation
      - Combined injuries will have greater than 12 mm increased posterior translation
      - Patients must be relaxed while the radiographs are taken.
        - "Guarding" by activating the quads can lead to false measurements
    - Films should be examined closely for avulsion fractures and tibial plateau fractures.
      - Pelligrini-Stieda (avulsion leading to heterotopic calcification) lesion at the femoral origin of the MCL
      - Seen in chronic MCL injuries
    - Lateral projections are useful to identify bony avulsions of the tibial attachment of the PCL.
- Chronic injury studies should include: Weightbearing AP, lateral at 45° flexion, Rosenberg view (Figure 33-10) and standing long leg radiographs and MRI
  - Radiographs should be carefully examined for tibial PCL insertion avulsion fractures that have not healed, or healed in malunion.
    - In addition, the physician should look for calcified lesions like the Pelligrini-Stieda lesion at the

FIGURE 33-9. External rotation recurvatum test. With the patient supine, stabilize the thigh and lift the great toe. Suspect combined injury if increased recurvatum.

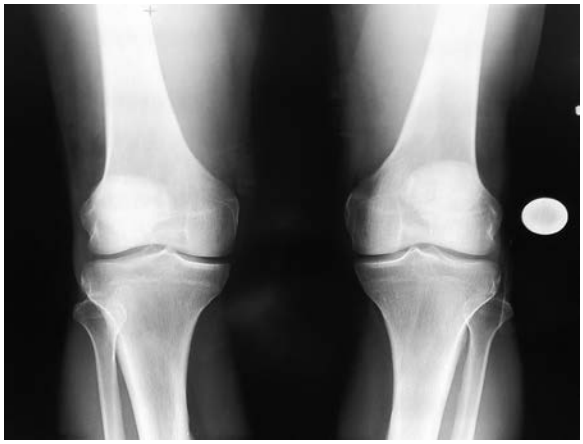

FIGURE 33-10. Rosenberg view radiograph.

femoral condyle, which would indicate a previous medial knee injury.
  - Standing long leg radiographs are used to assess joint alignment and help the practitioner decide the need for osteotomies before reconstruction of the damaged ligaments.
- Plain radiographs, including AP (weightbearing), lateral (at 45° flexion), oblique, sunrise, and Rosenberg views all may be useful.
- MRI → 97% sensitive for detecting acute PCL tears, but sometimes it can be difficult to tell if the tear is complete or partial. MRI can be inaccurate for chronic PCL injuries. This is where stress radiographs are useful.
  - Great for detecting combined injuries as well as assessing other ligaments/structures in the knee and subchondral bruising or damage
  - In chronic injuries, MRI of the PCL may appear normal as tears heal and scar, then the scar tissues can stretch out
  - Replaced the need for bone scans in patients with chronic PCL injuries suffering from pain and instability to look for early degenerative changes in the medial and patellofemoral compartments
    - Helps to influence surgical decision making

Differential Diagnosis

- PLC injury
  - Historical findings: Mechanism is typically hyperextension (contact or non-contact), direct trauma to the anteromedial knee or non-contact varus force to the knee
  - Physical findings: Pain, instability, swelling, positive posterolateral drawer sign/test, recurvatum test, varus stress tests at 0° and 30°, dial test, reverse pivot shift test, and figure 4 test. Also a varus thrust gait can be seen on gait analysis
  - ACL injury
  - Historical findings: Mechanism is typically valgus stress, or pop occurring while cutting, changing direction, landing (hyperextension pivot)
  - Physical findings: Pain, instability, swelling, positive Lachman sign/test
- MCL injury
  - Historical findings: Mechanism is valgus stress ± rotational stress
  - Physical findings: Pain and medial gapping with valgus stress testing; anteromedial drawer test
- Meniscal tear
  - Historical findings: Mechanism is typically a sudden twist on a weightbearing knee or repeated squatting
  - Physical findings: Intermittent pain at the joint line and possible joint locking, clicking, or catching. Meniscal tear assessment, Apley Test, posterior knee pain with knee flexion
- Tibial plateau fracture
  - Historical findings: Mechanism is typically a valgus force with axial loading, often from a fall or landing from height
  - Physical findings: Large effusion, palpable defect, varus or valgus instability, and severe pain

Treatment

An algorithm for deciding among surgical and nonsurgical treatment options is presented in Figure 33-11.

Nonoperative Management

- All modalities rely on physical therapy, and return to sporting activities is not typically allowed until full quadriceps strength has been restored and a firm end point on clinical exam is achieved (typically 6 to 8 months, but for elite athletes the timeframe could be as little as 6 to 8 weeks)
  - Slower rehabilitation protocols than those for ACL injuries

1. Immobilize the affected limb in extension for 2 to 4 weeks using a splint with a pad placed under the tibia to counter gravity (Figure 33-12)
   - Maintaining the tibia in the proper anatomical position is critical for maximizing healing potential.
   - Immobilizing in extension takes the tension off of the anterolateral bundle.
   - Physical therapy during the first 6 weeks focuses on reduction of inflammation (NSAIDs), maintaining ROM with prone passive flexion.
     - Patients should be doing straight leg raises, quadriceps sets, and partial weightbearing with crutches to maintain quadriceps strength.
   - Hamstring exercises should be avoided for at least 3 months.
   - Quadriceps strengthening is essential, can use PT or electrical stimulation
2. Jung et al.[3] put patients in a cylindrical cast for 6 weeks followed by a brace for 6 more weeks.
   - All 12 weeks utilized support against posterior tibial sag.
     - After 12 weeks physical therapy begins.
     - Straight leg raises and quad strengthening are recommended while casted.
   - After the cast is removed, patients start closed, kinetic exercises while preventing posterior displacement.
   - Flexion of up to 90° is allowed for the third week after cast removal and up to 120° by 6 to 12 weeks after cast removal.
3. Quadriceps strengthening with/without activity modification
4. Reduction of physical activity and/or MRI
5. Jack brace (Figure 33-13)
   - Allows full range of motion within the brace from 0° to 110° of flexion
   - Maintains anteriorly directed force on the posterior proximal tibia which prevents posterior sag and allows the PCL to heal in the proper position
   - Typically worn for 4 months
   - Only allowed to be taken off when the knee will be in full extension with the quads contracted (like standing in a shower) or prone full knee extension

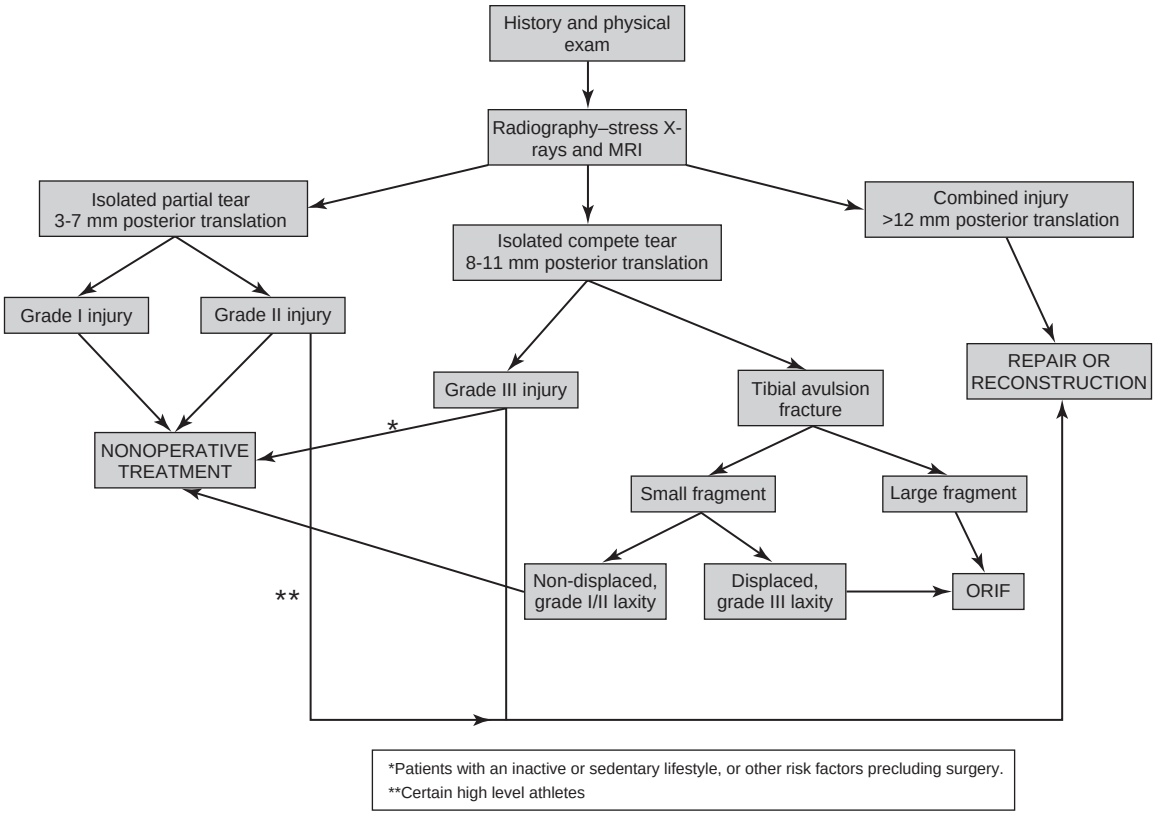

FIGURE 33-11. Flow chart of decision making for surgical versus nonsurgical treatment.

Guidelines for Choosing Among Nonoperative Treatments

- An optimal set of guidelines for nonoperative management of PCL injuries has not yet been defined or agreed upon.
- Combined PCL injuries are treated surgically.
- For nonsurgical treatment, patients should meet the criteria for isolated PCL injury:
  - PCL stress radiographs less than 8 mm
  - Less than 5° of abnormal rotary laxity at 30° knee flexion
  - No significant collateral injury causing varus/valgus laxity
- Isolated grade I or II PCL tears or a non-displaced PCL bony avulsion with a small fragment with grade I/II laxity can be treated with progressive weightbearing and rehabilitation focused on quadriceps strengthening.
  - Use of a Jack brace has been shown to provide good to excellent results in this patient population.
- Isolated grade III injuries can be immobilized in extension for 2 to 4 weeks followed by progressive weightbearing and therapy.
  - Therapy is focused on increasing ROM and quadriceps strengthening.
  - Elite athletes or those who fail conservative therapy should be considered for surgery.
- Grade III injuries in patients with an inactive or sedentary lifestyle: Typically these patients should not have surgery and should undergo appropriate nonoperative management, including quadriceps strengthening with or without activity modification.
- Patients with grade II injuries who develop recurrent pain and swelling should reduce physical activity until the pain and swelling subside.
  - May also require an MRI to gauge the status of the joint, articular cartilage, and meniscal cartilage
- Patients with chronic isolated or combined PCL injuries may require MRIs to gauge injury progression and dictate treatment modifications

FIGURE 33-12. Immobilizer brace for rehab patients.

Surgical Indications

Absolute

- PCL stress radiograph posterior translation greater than 12 mm
  - Indicates a combined ligament injury

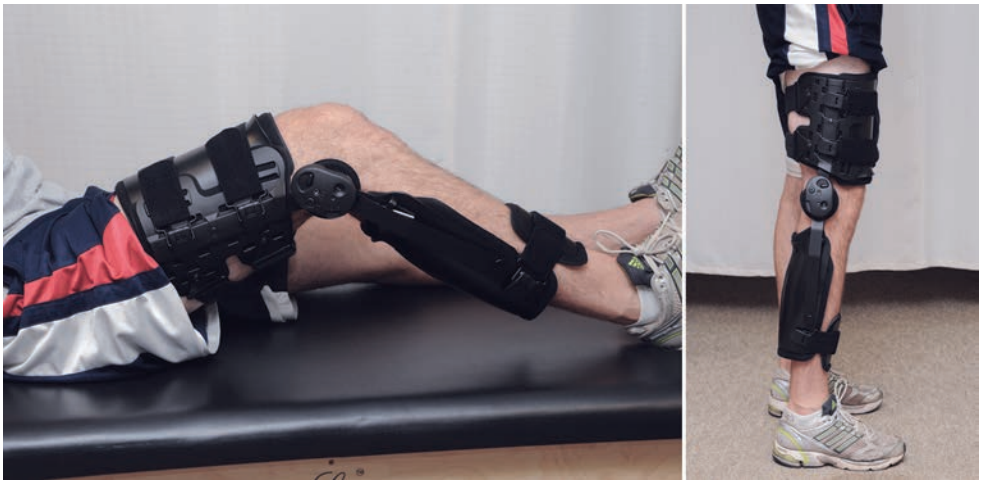

FIGURE 33-13. Jack PCL brace maintains anteriorly directed force on the posterior proximal tibia which prevents posterior sag and allows the PCL to heal in the proper position.

- Acute isolated PCL injury:
  - Grade III tears with plateau posterior to condyle
  - Bony avulsions that are displaced
  - Significant/symptomatic laxity (not confined to PCL only)
  - Associated meniscal injuries
- Especially medial meniscal root tears
- Acute combined PCL injuries:
  - Combined grade III PCL/PLC or PCL/PMC injuries should be treated surgically, typically will require reconstruction via a single or double bundle method
  - Multiligament repairs should be reconstructed concurrently and not as a staged procedure
- Chronic isolated PCL injury:
  - Symptomatic instability/pain
  - Early stages of arthrosis
- Large or displaced PCL tibial avulsions should be treated with operative fixation
- Symptomatic grade III tears
- Failure of conservative/nonoperative treatment

Relative

- Grade III tears with comorbidities
- Grade II tears in elite athletes to prevent medial and patellofemoral arthrosis and laxity following nonoperative treatment
- Small fragment bony avulsions with a high degree of laxity
  - Exceptions to surgery are patients with low physical demands or medical issues that would exclude operations or anesthesia

Aspects of History, Demographics, or Exam Findings That Affect Choice of Treatment

- Grade I and II injuries are not typically treated surgically, whereas most grade III injuries are reconstructed or repaired.
- Patient who will not comply with postsurgical protocol should not be treated surgically.
- Combined injuries found on exam are treated surgically.
  - Typically require reconstruction if chronic (greater than 3 weeks)
  - Not recommended to be done as a staged procedure
- Complete midsubstance tears can be reconstructed via a single bundle, double bundle, or tibial inlay technique.
- Large bony avulsion injuries or those that are displaced should be treated surgically (open reduction internal fixation).
- Studies have shown that PCL-deficient knees tend to have altered load bearing patterns and contact areas, especially in the patellofemoral and medial compartments, which could lead to degenerative joint disease and disability.
- Practitioners should be cautious when considering whether to treat patients with sedentary, inactive lifestyles surgically.
  - Patients will have to adhere to a strict postoperative physical therapy protocol to achieve optimal results.
  - Patients who are likely to be noncompliant should be screened accordingly.

Aspects of Clinical Decision Making When Surgery Is Indicated

- The time frame for surgery for acute combined PLC/PCL injuries should take place within 3 weeks of the initial injury to avoid fixed posterior subluxation and capsular scarring if possible.
  - Acute isolated injuries to the PCL that will require surgery are best reconstructed early.
- The location of the injury and the degree of laxity are major factors that play a role in determining the necessity of surgery.
  - Large bony avulsions and combined PCL/PLC injuries should be treated early if found.
- Patients with grade I and II injuries can be managed nonoperatively, but isolated grade III injuries are controversial.
  - Most surgeons believe that grade III injuries increase pressures in the medial compartment and can lead to early arthritis.

  - Younger patients with grade III tears are typically managed surgically to prevent the development of arthritis even though there has been no definitive study showing it to be beneficial.
- Almost all combined grade III tears are repaired by repair/reconstruction of the damaged PCL and reconstruction/repair of the other damaged structures depending on the severity and location of the injury.
- Some patients who require surgery present with a fixed posterior subluxation.
  - Typically seen in patients with a previous failed PCL reconstruction or patellar tendon harvest and a long history of PCL insufficiency
  - Patients with grades I and II fixed posterior subluxations should be treated with a functional PCL brace to reposition the tibia before surgery.
  - Patients with grade III fixed posterior subluxation may require more invasive procedures such as a posterior capsulotomy before having their PCL reconstructed to avoid stretching of the graft after surgery.
- Head injuries, vascular traumas, soft tissue status, and general medical comorbidities must be taken into account before deciding on the appropriate treatment

Evidence

Fanelli GC: Posterior cruciate ligament injuries in trauma patients. *Arthroscopy* 9:291–294, 1993.
Fanelli GC, Edson CJ: Posterior cruciate ligament injuries in trauma patients: Part II. *Arthroscopy* 11:526–529, 1995.

A two part prospective cohort analysis of the incidence of PCL injuries in patients presenting to a trauma center with acute knee hemarthrosis. The study found PCL injuries in 38% of cases with 56% being trauma related and 33% were sports related. (Level I evidence)

Jung YB, Tae SK, Lee YS, et al: Active non-operative treatment of acute isolated posterior cruciate ligament injury with cylinder cast immobilization. *Knee Surg Sports Traumatol Arthrosc* 16:729–733, 2008.

Prospective study of 17 acute and isolated PCL injuries with at least 2 years follow-up for each patient. Patients were put in full extension in a cylinder cast for 6 weeks followed by 6 weeks in an immobilizer brace with tibial supporter. The authors found improved anteroposterior stability and clinical results with some residual laxity. Concluded that conservative treatment making use of a cylinder cast and immobilizer brace could be a recommendable nonoperative treatment modality for isolated and acute PCL injuries. (Level III evidence)

Kennedy JC, Hawkins RJ, Willis RB, et al: Tension studies of human knee ligaments. Yield point, ultimate failure, and disruption of the cruciate and tibial collateral ligaments. *J Bone Joint Surg Am* 58(3):350–355, 1976.

Cadaver study to determine failure strengths of human FCL, ACL and PCL using an Instron Tension Analyzer. Found the PCL to be was significantly stronger than the FCL (LCL) and ACL, which were of equal strength. Discovered the ligaments were intact macroscopically but electron microscopy revealed disruption of the collagen fibrils at ultimate failure. This signifies that microscopic failure of the collagen fibrils in grossly intact ligaments may be a cause of clinical instability. (Cadaver study)

Khoschnau S, Melhus H, Jacobson A, et al: Type I collagen α1 Sp1 polymorphism and the risk of cruciate ligament ruptures or shoulder dislocations. *Am J Sports Med* 12(36):2432–2436, 2008.

Case control study that examined 358 patients with soft tissue injuries versus 325 random female controls using unconditional logistic regression to determine if persons with a mutation to the COL1A1 gene was less likely to suffer a soft tissue injury. The ss genotype was found to be less likely to sustain soft tissue injuries.(Level III evidence)

Lein OA, Aas EJ, Johansen S, et al: Clinical outcome after reconstruction for isolated posterior cruciate ligament injury. *Knee Surg Sports Traumatol Arthrosc* 18:1568–1572, 2010.

This prospective trial followed 43 patients to discover clinical outcomes following surgery with reconstruction for an isolated PCL injury. At 48 months, Lysholm knee scores, International Knee Documentation Committee 2000 (IKDC) scores, Cincinnati scores, Tegner scores, KOOS scores, VAS scores, stress radiographs, and functional tests showed good functional outcomes following reconstruction. (Level III evidence)

MacDonald P, Miniaci A, Fowler P, et al: A biomechanical analysis of joint contact forces in the posterior cruciate deficient knee. *Knee Surg, Sports Traumatol Arthroscop* 3:252–255, 1976.

A biomechanical study that compared nine fresh cadaveric knees from young donors as they were loaded at 0°, 30°, and 60° to 1.5 kN with low-pressure sensitive Prescale film inserted through arthrotomies into the medial and lateral compartments. Computerized analysis of the imprints on the film was then carried out and repeated after cutting the PCL. Results showed a statistically significant posterior subluxation of the tibia on the femur at 60° flexion leading to a significant increase in pressure at the medial compartment after cutting the PCL. These findings may explain long-term degenerative changes at the medial femoral condyle in PCL deficient knees. (Cadaveric study)

Parolie JM, Bergfeld JA: Long-term results of nonoperative treatment of isolated posterior cruciate ligament injuries in the athlete. *Am J Sports Med* 14(1):35–38, 1986.

Long-term study of 25 athletes who received nonoperative treatment of isolated PCL injuries with follow-up averaging 6 years. Patients were evaluated with a questionnaire and objectively with clinical examination, x-ray films, Cybex II dynamometer, and KT-1000 Knee Arthrometer. Found that 80% of the patients were satisfied with their knee with 84% returning to their previous sport. It was concluded that if athletes with isolated PCL injuries maintain muscle strength, the majority should return to sports without lingering disability. (Level IV evidence)

Schulz MS, Russe K, Weiler A, et al: Epidemiology of posterior cruciate ligament injuries. *Arch Orthop Trauma Surg* 123:186–191, 2003.

A retrospective analysis of 494 patients with PCL insufficiency using stress radiographs to quantify posterior tibial displacement to understand the epidemiology of PCL Injuries. The authors found that athletic injuries represented 40% of this cohort, with the majority of these resulting from contact sports. (Level II evidence)

Shelbourne KD, Jennings RW, Vahey TN: Magnetic resonance imaging of posterior cruciate ligament injuries: Assessment of healing. *Am J Knee Surg* 12(4):209–213, 1999.

This study followed 40 knees with acute PCL injuries during the initial 6 months to and approximately 3 years later to assess healing demonstrated on T2 MRI. Found that all of the low and mid-grade PCL injuries had healed with continuity, whereas 19 of 20 high-grade and combined injuries were showed healing, but were less likely to regain continuity. Concluded that most nonoperatively treated PCL tears can heal with continuity, even when accompanied by other ligament injuries. (Level III evidence)

Strobel MJ, Weiler A, Schulz M, et al: Fixed posterior subluxation in posterior cruciate ligament-deficient knees. *Am J Sports Med* 30(32):32–38, 2002.

This study examined found that 109 of 248 patients with PCL insufficiency suffered from fixed posterior subluxation of the tibia. Patients were treated with a posterior tibial support brace to reduce subluxation. The investigators found that the brace reduced subluxation well in patients with grades I and II subluxations, but not sufficiently in patients with grade III subluxation. They concluded that patients with grades I and II subluxations should be treated with a posterior support brace before PCL reconstructions, whereas those with grade III subluxation should receive more invasive treatments prior to reconstruction. (Level III evidence)

Winters K, Tregonning R: Reliability of magnetic resonance imaging of the traumatic knee as determined by arthroscopy. *N Z Med J* 118(1209):U1301, 2005.

A prospective study comparing the diagnostic results of MRI scans of 67 patients with knee injuries with subsequent arthroscopic diagnosis. The imaging studies provided a diagnostic accuracy of 96% for posterior cruciate ligament injuries with a sensitivity of 80% and specificity of 97%. It was concluded that MRI is a useful diagnostic tool for evaluating knee injuries. (Level II evidence)

Multiple Choice Questions

QUESTION 1. A 25-year-old male soccer player slid into the goalpost while making a save. He suffered a direct anterior blow to the proximal tibia of his flexed left leg. He presented to the hospital that night with pain and swelling of the left knee. He described a general feeling of "something not being right" and had difficulty walking down stairs. On clinical examination he was discovered to have a Grade III PCL tear. Which of the following is the most important aspect to evaluate in a patient presenting with an acute knee injury?

A. Posterior drawer test
B. MRI with axial cuts
C. Posterior knee stress radiographs
D. Neurovascular status

QUESTION 2. If a patient had suffered an isolated posterior cruciate ligament tear, which of the following abnormal motions would be seen on physical exam?

A. The tibia would move anteriorly in relation to the femur.
B. The knee would have lateral opening when a valgus stress is applied.
C. The tibia would move posteriorly in relation to the femur.
D. The knee would lock in extension.

QUESTION 3. Which of the following patients should not be considered for surgical repair or reconstruction of a PCL injury?

A. A 25-year-old elite athlete with a grade II PCL tear
B. A 19-year-old patient with an acute combined grade III PCL/PLC injury with hemarthrosis of the affected knee
C. A 35-year-old female with a large bony avulsion off the tibia
D. A 58-year-old obese, sedentary male with an isolated grade III tear of his PCL

QUESTION 4. During first 6 weeks of rehabilitation or nonoperative treatment of posterior cruciate ligament injuries, which of the following exercises should be avoided?

A. Isolated hamstring strengthening exercises
B. Straight leg raises
C. Electrical stimulation of the quadriceps muscles
D. Partial weightbearing on crutches

QUESTION 5. A 45-year-old male hockey player comes into the office complaining of generalized pain in his left knee after sliding into a goal post during a recreational hockey game 1 week ago. He has no numbness, tingling, or loss of sensation in the affected limb. After completing a complete physical exam, you suspect he has suffered an isolated PCL injury. If an MRI scan were unable to determine if the tear is partial or complete, which diagnostic modality would be most helpful in classifying his injury?

A. Tunnel view radiographs
B. Posterior stress radiographs
C. AP and lateral radiographs
D. CT imaging

Answer Key

QUESTION 1. Correct answer: **D** With acute knee injuries it is of vital important to determine a patient's neurovascular status. The examiner must make certain there has been no damage to arteries or nerves which would require immediate intervention to prevent permanent loss or disability. (see Clinical Presentation)

QUESTION 2. Correct answer: **C** The tibia would move posteriorly in relation to the femur. With isolated PCL injuries, the main posterior stabilizer preventing

posterior translation of the tibia is lost. In combined injuries you can see increased rotatory instability as well as medial/lateral gapping. Locking in extension/flexion is more typical of meniscal injuries and would not be expected in an isolated PCL injury. (see Clinical Presentation)

QUESTION 3. Correct answer: **D** Patients with a sedentary lifestyle, or those who are unlikely to comply with rehabilitation and postoperative protocols should not be considered for PCL reconstruction, even with grade III tears. Elite athletes with grade II tears can be considered for surgery to aid them in returning to the previous level of performance. Large bony avulsion fractures are candidates for surgery, whereas smaller avulsions can be managed conservatively. Acute combined PCL injuries are typically candidates for surgery within 3 weeks of the injury, even if hemarthrosis is present. (see Treatment)

QUESTION 4. Correct answer: **A** Isolated hamstring exercises create posterior forces on the tibia, which can stretch reconstruction grafts or reinjure partial tears. Patients should avoid isolated hamstring exercises for at least 8 weeks after injury or surgery to allow for adequate healing. Straight leg raises, electrical stimulation, and partial weightbearing on crutches are all strategic points in the initial phase of surgical rehab or conservative treatment. (see Treatment)

QUESTION 5. Correct answer: **B** Posterior stress radiographs are a helpful diagnostic tool to objectively assess PCL tears. Normal knees have between 0 and 2 mm increased posterior translation, partial tears 2 to 7 mm, complete tears 8 to 11 mm and combined injuries will have greater than 12 mm increased posterior translation. They can be very helpful when the clinical exam or an MRI is nondiagnostic. Tunnel view radiographs, AP, and lateral radiographs are all part of the imaging work-up for a suspected PCL injury, but are of no use when grading the tear. Computed tomography has little use with PCL injuries unless the surgeon is trying to assess the size of an avulsion fracture for operative planning or is looking for a tibial plateau fracture. (see Imaging)

NONOPERATIVE REHABILITATION OF POSTERIOR CRUCIATE LIGAMENT INJURIES

Robert F. LaPrade, MD, PhD, Casey M. Pierce, MD, and Scott A. Wilkins, DPT, OCS

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- Protect healing ligament.
- Reduce swelling and pain.
- Restore functional strength and stability to the knee.
- Initiate early activation of the quadriceps to maintain stability.
- Limit risk or reinjury.
- Help the patient adapt to daily life after injury and safely return to sports.

Phase I (weeks 0 to 4)

Protection

- Nonweightbearing (NWB) to partial weightbearing for 2 weeks
- Axillary crutches until gait is normalized
- Knee immobilizer locked in 0° extension during gait for first 1 to 2 weeks (Figure 33-14*A*)
  - Pad behind tibia to avoid posterior tibial sag while at rest (Figure 33-14*B*).
  - Brace opened to 90° for sitting after 2 weeks.
  - Knee ROM should be performed only in the prone position for the first week (Figure 33-15).
    - Prevents hamstring activation and posterior sag caused by gravity
- If a combined PLC and PCL injury is diagnosed, the patient should be in a functional PCL brace to better support the posterior capsule.
- Range of motion during therapy exercises should be limited from 45° to 90° for the first 2 weeks.
  - This is based on biomechanical studies that show the varying loads on the PCL based on knee flexion angles and avoidance of sheer forces on the damaged PCL.

Management of Pain and Swelling

- Vasopneumatic compression
- Elevation
- Compression bandage
- Cryotherapy
  - Apply ice for 20 minutes following exercises/physical therapy
- PRICE technique → protect, rest, ice, compress, and elevate

FIGURE 33-14. Knee Immobilizer locked in 0° extension (**A**) and pad behind tibia to avoid posterior tibial sag while at rest (**B**).

- Medications
  - NSAIDs as needed
- 48 hours after the injury moist heat can be applied for 20 minutes at a time as needed

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Initially patients are immobilized to allow for early ligament healing to begin (see Figure 33-14).
- Protected prone ROM may begin right away depending on the grade of the injury or other associated injuries.
  - Posterior sag of the tibia must be protected at all times during this phase.
  - Once ROM is allowed, passive ROM is progressed slowly over the next 4 weeks from 0° to 120°.
  - Knee ROM should be performed passively in the prone position (see Figure 33-15).
    - Avoids activation of the hamstrings
    - Allows compression of the tibiofemoral joint preventing posterior translation of the tibia on the femur
    - Prevents posterior sag of the tibia on the femur
  - Passive knee flexion should be performed with a manual anteriorly directed translation force on the tibia over the femur throughout the range of motion.
- Anteriorly directed tibial translation mobilizations may be performed in chronic injuries that have a fixed posterior translation to restore normal joint position and tibiofemoral contact points.
- Patellar mobilizations can be performed during the immobilization period to avoid adhesions of the patellofemoral joint.

FIGURE 33-15. ROM exercises in the prone position with anteriorly directed tibial translation.

FIGURE 33-16. Stretching exercises for the hamstring (**A**), gastrocnemius (**B**), and quadriceps (**C**).

Soft Tissue Techniques

- Soft tissue mobilization, trigger point release, myofascial release, and retrograde edema mobilization may be performed on the muscles and fascia around the involved limb.
  - These techniques reduce fascia restrictions, control swelling, reduce pain, and facilitate muscle activation.
  - To limit stress to the healing ligament, care should be taken during soft tissue techniques to avoid direct posterior pressure on the tibia or varus/valgus positioning of the limb.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Stretching of the posterior thigh, hamstring and gastrocnemius muscles as tolerated without pain (Figure 33-16).
  - Especially warranted for those individuals demonstrating a flexed knee gait

Other Therapeutic Exercises

- Total leg strength (TLS)
  - Two sets of 10 to 15 repetitions for lower extremity strengthening exercises
  - Straight leg raise in supine with brace on and locked in extension (Figure 33-17)
  - Standing/side-lying hip abduction with brace on (Figure 33-18)

FIGURE 33-17. Supine straight leg raise with locked extension brace.

FIGURE 33-18. Side-lying hip adduction with the brace in place.

- Standing/prone hip extension with brace on (Figure 33-19)
- Standing heel raises once weightbearing is allowed (Figure 33-20)

- Total body strength (TBS)
  - Upper body strengthening and core strengthening may continue throughout this phase in a nonweightbearing position.
    - Care must be taken to avoid bracing or stabilizing with the involved limb during upper body and core strengthening.
    - The knee brace should be worn for safety.
  - Early TBS exercises
    - Two sets of 8 to 12 repetitions for upper extremity and core strengthening exercises
    - Posterior pelvic tilting with abdominal bracing (Figure 33-21*A*)
    - Abdominal bracing with leg lifting in supine and prone (Figure 33-21*B*)
    - Seated rows with the legs straight
    - Seated pull downs with the legs straight
  - Rotational stresses to the core may be applied manually by the therapist and initiated in supine during Phase I.

FIGURE 33-19. Standing hip extension with the brace in place.

TIMELINE 33-1: **Nonoperative Rehabilitation of a Posterior Cruciate Ligament Injury**

PHASE I (weeks 1 to 2 postinjury)

- PWB with crutches until end of week 2
- Brace limiting ROM 0°–90°
  - Padding placed behind posterior tibia to prevent sagging at rest
  - Capsule support if combined injury
- Transition to Jack PCL brace when quad control allows normal SLR
- PRICE protocol and proper stretching
- PT modalities
- Passive prone ROM-flexion 0°–90°
  - Patellar mobilizations and anterior tibial translation mobilizations
- EMS to quadriceps
- TBS/TAS/TLS activities as recommended and tolerated
- OKC and CKC exercises
  - Quad sets
  - Quad isometrics Straight leg raises
  - Hip abduction/adduction
  - Knee extensions 90°–60°
  - Leg presses 0°–70°
- Avoid isolated hamstring activating exercises
- TBS/TAS/TLS activities as recommended and tolerated
- Stability exercises progression to unstable surfaces by week 3
- Upper body bike
- Stationary bike and pool program during week 3
- Gait mechanics after week 2

PHASE II (weeks 5 to 8 postinjury)

- Weightbearing as tolerated
- JACK brace
- PRICE protocol and proper stretching
- PT modalities
- ROM—week 3: Performed passively in prone 0°–90°
- ROM—week 4: Performed passively in prone 0°–120°
- ROM—week 6: Performed passively in prone 0° to full PROM
- OKC and CKC exercises with progressing weight
  - Quad sets
  - Quad isometrics
  - Straight leg raises
  - Hip abduction/adduction exercises
  - Knee extensions 0°–70°
  - Leg presses 0°–70°
  - Mini-squats 0°–70°
  - Step ups
  - Toe calf raises
- Hamstring activation beginning week 6
- Range 0°–70° with low resistance only
- TBS/TAS/TLS activities as recommended and tolerated
- Pool running week 5
- Running progression may begin week 6
- Deceleration exercises

FIGURE 33-20. Standing heel raises: two legs (**A**) and one leg (**B**).

TIMELINE 33-1: **Nonoperative Rehabilitation of a Posterior Cruciate Ligament Injury** (Continued)

PHASE III (weeks 9 to 14 postinjury)	PHASE IV (weeks 15 to 20 postinjury)	PHASE V (weeks 21+ postinjury)

• PT modalities as needed JACK brace
• PROM—full
• PRICE protocol and proper stretching
• Soft tissue techniques and joint mobilizations as needed PT modalities
• TBS/TAS/TLS activities as recommended and tolerated
• Quadriceps strengthening—PREs
• TAS—upper body strengthening—PREs-performed in sitting
• Hip—PREs
• Core strengthening/stabilization exercises
• Balance and proprioception exercises
• Neuromuscular dynamic stability exercises with brace on
• Straight-ahead running as tolerated
• OKC and CKC exercises with progressing weight
  • Quad sets
  • Quad isometrics
  • Straight leg raises
  • Hip ab/adduction
  • Knee extensions 0°–90°
  • Leg presses 0°–70°
  • Mini-squats 0°–70°
  • Step ups
  • Toe calf raises
• CKC exercises to 70° flexion, progressing to 90° by week 8
• Continued deceleration training
• Initiate plyometrics and jump training exercises
• Running progression including light cutting and pivoting by week 12
• Sport specific agility and skill training
• Gradual return to practice and sport activities
	• Clinical exam and/or PCL stress radiographs to verify healing of PCL
	• PCL brace with sporting activities
	• PT modalities as needed
	• PROM—full
	• Tool assisted soft tissue techniques and joint mobilizations as needed
	• TBS/TAS/TLS activities as recommended and tolerated
	• Hip—PREs
	• TAS—upper body strengthening- PREs—performed in standing
	• Core strengthening/stabilization exercises progressed
	• OKC knee exercises for quadriceps and hamstrings
	• CKC exercises to 90° knee flexion
	• Balance and proprioception exercises
	• Neuromuscular dynamic stability exercises with brace on
	• Progress running program
	• Sport specific agility exercises
		• PROM—maintain full motion
		• Mobilizations as needed
		• TBS/TAS/TLS activities as recommended and tolerated
		• OKC exercises progressed
		• CKC exercises progresses
		• Neuromuscular dynamic stability exercises without brace
		• Plyometric/jump training progressed
		• Sport specific agility exercises
		• Core strengthening/stabilization exercises progressed
		• Noncontact return to play after 24
		• Full contact return to play when return to sports criterion met

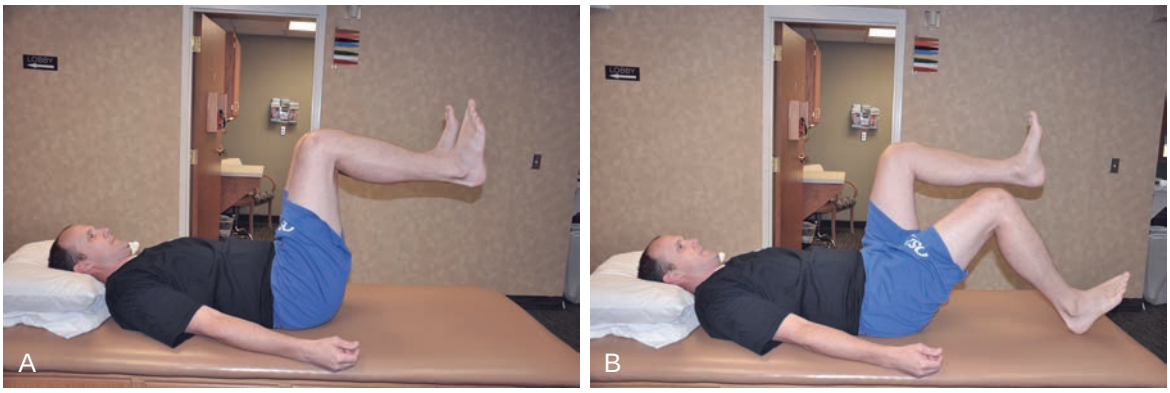

FIGURE 33-21. Posterior pelvic tilting with abdominal bracing (**A**) and with one leg lifting (**B**).

Activation of Primary Muscles Involved

- Quadriceps activation through quadriceps setting and progressing to straight leg raising without an extension lag
  - Two sets of 10 to 15 repetitions
  - This should be performed in the knee brace with pad behind tibia to avoid posterior tibia sag.
  - Patient may progress to straight leg raise without the brace once able to perform exercise without a lag sign
- Neuromuscular electrical stimulation may be applied to quadriceps to aid in early activation and prevent atrophy of immobilized muscles (Figure 33-22)
  - Also found to be useful when applied while the patient exercises

Sensorimotor Exercises

- Once weightbearing is allowed, patients may initiate standing weight shifts with their brace on.
  - May progress to exercises without the brace once the patient has demonstrated normal quadriceps activation, straight leg without lag sign, and can bear full weight without pain or giving way
- Single leg exercises help to restore balance
- Balance exercises are progressed from eyes open to eyes closed and from stable to unstable surfaces such as foam pads.
- The majority of proprioceptive training will begin during Phase II.

Open and Closed Kinetic Chain Exercises

- OKC exercises while in brace
  - Two sets of 10 to 15 repetitions for OKC exercises
  - Side-lying or standing hip abduction
  - Standing or prone hip extension
  - Supine straight leg raises
  - Ankle pumps
- Once knee ROM is allowed, OKC exercises can include:
  - Knee extension from 90° to 60° flexion to facilitate quadriceps strengthening (Figure 33-23)
    - Limit knee extension to decrease forces on the patellofemoral joint and sheer forces on the healing PCL

FIGURE 33-22. Electrical stimulation pad placement on the quadriceps.

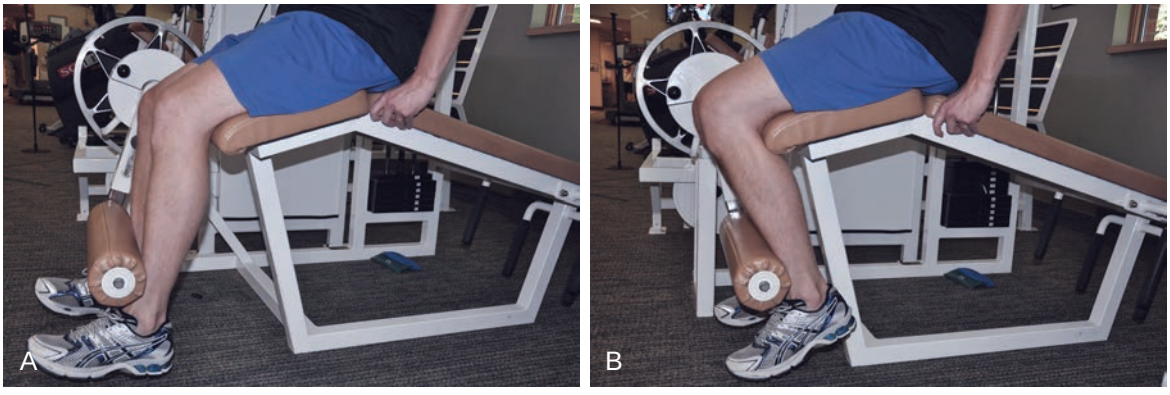

FIGURE 33-23. OKC knee extensions from 90° (**A**) to 60° (**B**).

FIGURE 33-24. Two legged wall slides from 0° to 70°.

- CKC exercises may begin after 2 to 3 weeks or once weightbearing is allowed
  - Limit knee extension between 70° and 30° window to limit forces on the patellofemoral joint and sheer forces on the healing PCL
  - Early exercises
    - Two sets of 10 to 15 repetitions for early exercises
    - Standing heel raises
    - Two-legged wall slides from 0° to 70° (Figure 33-24)
    - Leg press at 25% body weight (Figure 33-25)
  - 25% body weight is a starting point for CKC exercises that may be progressed according to patient tolerance and performance of exercise at an intensity of two sets of 10 to 15 repetitions
  - Limited to 45° knee flexion for the first week and progressed to 70° during week 2
    - Prevents posterior sheer forces on the PCL
  - Progress to mini squats at the counter from 0° to 70°

FIGURE 33-25. Leg presses at 45°.

Techniques to Increase Muscle Strength, Power, and Endurance

- OKC and CKC exercises can be progressed according to patient tolerance and endurance
  - Mixed CKC and OKC quadriceps will help build strength/power
  - Single leg resisted knee exercises can start after week 1
  - Exercises should be pain free
  - Exercises are discontinued if pain, acute effusion, catching, or giving way is present
- Early exercises should include high repetition and low weight resistance to target Type I endurance muscle fibers
  - An upper body bicycle can be helpful to maintain or improve cardiovascular endurance
- Strengthening exercises should be performed daily or every other day and monitored for signs of joint aggravation such as acute swelling/effusion and localized joint pain

Neuromuscular Dynamic Stability Exercises

- CKC neuromuscular stability exercises should be performed in the brace initially until normal quadriceps activation (as compared with the contralateral normal side) is achieved and the patient is able to walk without a limp.
  - Stability exercises should progress from stable to unstable surfaces such as foam, air bladders, or wobble boards (Figure 33-26).
    - Three to five sets of 30 second intervals for stability exercises
  - Patients may initially require upper extremity assistance to maintain balance.
  - As function and stability progress, perturbations may be applied in random order to further challenge the neuromuscular system.

Functional Exercises

- Step up exercises performed on a 6-inch step can begin when gait on flat ground is normalized (Figure 33-27).
  - Two sets of 10 to 15 repetitions for step up exercises
- Exercises should be performed with the brace on and can be progressed through increased step height and from stepping up to stepping down.
- Walking forward and backward with the help of a mirror will help to restore proper gait mechanics once full weightbearing is allowed

Milestones for Progression to the Next Phase

- Minimal or decreased knee swelling
- Ability to straight leg raise without extension lag
- Gait is normalized without crutch assistance
- Patient is able to walk up and down steps without limp
- Knee ROM to 120° flexion

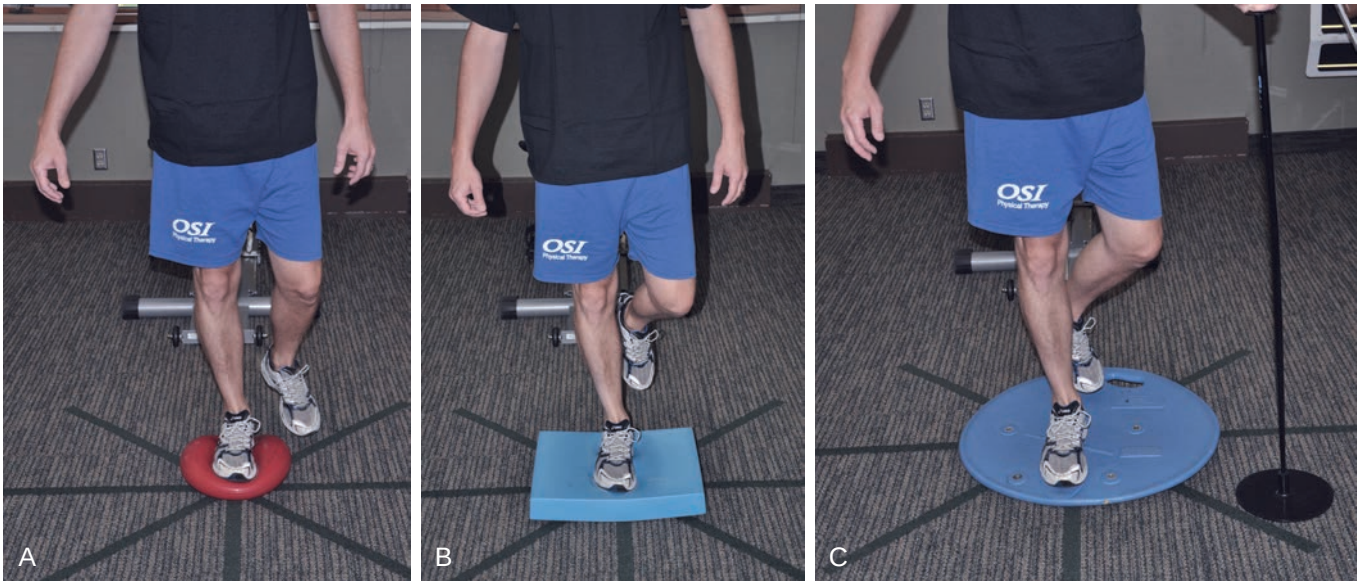

FIGURE 33-26. Stability exercises on an air bladder (**A**), foam (**B**), and wobble board (**C**).

Phase II (weeks 5 to 8)

Protection

- Transition to PCL support brace
  - Used for support during light activities and pain free return to sports activities
- Discontinue the use of crutches
  - Weightbearing as tolerated

Management of Pain and Swelling

- Similar to Phase I
- Vasopneumatic compression
- Elevation
- Compression wrap
- Cryotherapy
  - Apply ice for 20 minutes following exercises/physical therapy
- PRICE technique → protect, rest, ice, compress, and elevate
- Medications
  - NSAIDs as needed
- Moist heat can be applied for 20 minutes at a time as needed

Techniques for Progressive Increase in Range of Motion

- Progress toward full PROM starting at week 4 followed by full AROM once isolated hamstring contractions are allowed at 6 weeks.

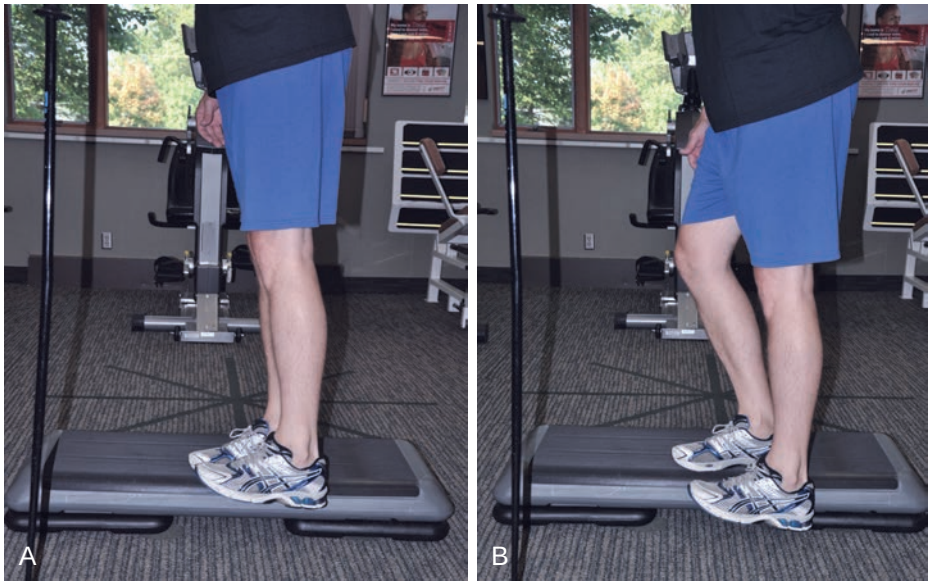

FIGURE 33-27. Step up exercises: start (**A**) and finish (**B**).

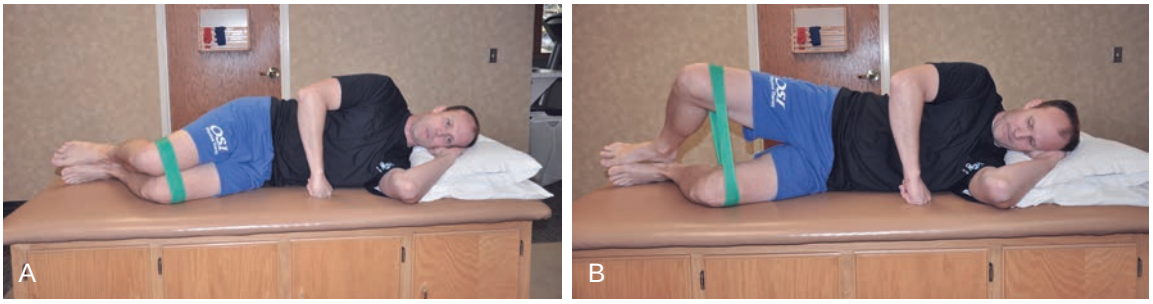

FIGURE 33-28. Side-lying external rotation (clamshell): start (**A**) and finish (**B**).

- Posterior sag of the tibia must continue to be avoided through an anteriorly directed force applied to the tibia during all ROM exercises and avoidance of isolated hamstring activation.

Manual Therapy Techniques

- Anterior tibial translation mobilizations and patellar mobilizations as needed to restore normal tibiofemoral contact points and prevent fixed posterior translation of the tibia
- Continued patellar mobilizations may be required as full knee flexion ROM is achieved

Soft Tissue Techniques

- Continue as necessary from Phase I.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Passive range of motion (PROM) performed in a prone position, or in a supine position with anteriorly directed force applied to the posterior tibia during flexion to achieve the goal of full PROM
- Hamstring and calf stretching as needed
- Begin prone quad stretching as full knee flexion ROM is achieved

Other Therapeutic Exercises

- Weight or resistance bands may be added proximal to the tibia as strength allows
- TLS should be performed to fatigue every other day
- TLS exercises should continue to include:
  - Quadriceps sets
  - Supine straight leg raises into hip flexion
  - Side-lying hip abduction
  - Prone hip extension
  - Side-lying hip "clamshell" external rotation (Figure 33-28), and standing single leg heel raises
  - Each exercise should be performed three times per day to fatigue
- Stationary biking for ROM may begin once 105° of knee flexion is achieved (Figure 33-29)
  - Seat height should be set so that the lower leg should have the knee slightly flexed at bottom dead center of the pedal stroke
  - The foot should be placed slightly forward on the pedal (without toe clips) to minimize hamstring activity
  - Start with no resistance
  - Progress from 5 minutes to 20 minutes as strength permits

FIGURE 33-29. Proper leg placement on a stationary bike. To avoid activation of the hamstrings, the patient should ride the bike with the seat set to allow the knee to flex slightly (**A**) and the feet slightly forward on the pedals (**B**).

- Core stability exercises may now incorporate the use of the lower body for stabilization:
  - Two sets of 10 to 15 repetitions for core stability exercises
    - Isometric hold exercises such as planks may be performed in two to three sets of 30- to 60-second hold intervals
  - Standing isometric side planks and side-lying planks
  - Bridging progression
  - Swiss ball work
- Patients should avoid kneeling on the affected limb.
  - Quadruped strengthening exercises are avoided.
- Isolated hamstring activation is not allowed; therefore, stability exercises such as 90/90 bridging or heel digs must also be avoided.
- TBS exercises can include upper body strengthening in weightbearing with brace on for protection.
  - Patients should maintain an athletic stance with equal weight distribution throughout the lower extremities during upper body exercises.
  - Resistance should be limited to levels conducive to proper form throughout the upper and lower body.

Activation of Primary Muscles Involved

- Quadriceps
- Gluteal muscles
- Gastrocnemius

Sensorimotor Exercises

- Weight shifting and single leg stance exercises can be progressed from flat ground to unstable surfaces such as foam pads, half-foam roller, rocker boards, and air bladders
  - Two to three sets of 30- to 60-second hold intervals for sensorimotor exercises
- Emphasis is placed on maintaining neutral knee alignment and athletic stance during balance exercises
- Exercises should be performed with brace on for additional safety
- Balance exercises can be further progressed by closing the eyes or applying manual perturbations
- Single leg exercises should be increased

Open and Closed Kinetic Chain Exercises

- Open kinetic chain knee extension for quadriceps strengthening may begin at the end of week 2 and continue throughout rehabilitation, ranging from 70° to 30° of extension, in a sitting position
- Open kinetic chain knee flexion and isolated hamstring activation is not allowed until after week 6
  - When starting leg curls/isotonic hamstring curls, range only from 0° to 70° and begin with very light resistance
- Supine straight leg raise, side-lying hip abduction, prone hip extension, side-lying hip external rotation (clamshell) OKC strengthening should continue throughout Phase II
- CKC exercises can be increased from Phase I (two sets of 8 to 12 repetitions)
  - Leg press 0° to 70° increasing to 60% to 80% body weight
  - Squats to 70° knee flexion
  - Single leg squats to 70° flexion
  - Forward and backward lunges (Figure 33-30)
  - Resisted toe calf raises
  - Step ups and step downs
  - Single leg wall slides to 70° knee flexion

FIGURE 33-30. Forward/Backward lunges.

Techniques to Increase Muscle Strength, Power, and Endurance

- Exercises for endurance can be initiated as ROM and discomfort allow
  - 20- to 30-minute intervals three to five days per week at 65% to 70% of age predicted maximum heart rate
    - Begin initially with 10 minute bouts three times per day until 20 to 30 minutes of exercises is tolerated for endurance exercises
  - Resisted cycling is progressed as endurance allows
    - Patients should maintain greater than 80 RPMs and quadriceps should feel fatigued after cycling, not completely exhausted
  - Elliptical
  - Stairmaster
  - Pool running/pool program

Neuromuscular Dynamic Stability Exercises

- Two sets of 8 to 12 repetitions for neuromuscular dynamic stability exercises
- Deceleration drills to teach proper landing technique should begin during Phase II
  - Double leg landings
    - Make sure the patient holds the landing position for 3 to 5 seconds

FIGURE 33-31. Squat jumps progression.

- Squats on a tilt board or balance ball
- One-legged balance throws
- Balance lunges on a tilt board
  - Can increase difficulty by adding perturbations

Plyometrics

- Two sets of 8 to 12 repetitions per exercise for plyometric exercises
- Deceleration/landing exercises should be mastered prior to moving on to plyometric exercises:
  - Side to side jumps
  - Jumping jacks
  - Squat jumps (Figure 33-31)

Functional Exercises

- Before progressing to running the patient must be able to walk aggressively at approximately 4.2 to 5.2 MPH without pain
  - Progression of marching skipping, high knees, and bounding performed at three sets of 30-second intervals until 450 foot contacts are achieved would be equivalent to two thirds of a mile
- Running progression should start during week 6
  - Marching → skipping → high knees → alternate leg bounding
- Squatting is progressed to a depth of 70° knee flexion
  - Patients should be told to avoid excessive forward lean during squats because this increases hamstring activation relative to the quadriceps
- Single leg squats to a depth of 70° are initiated with the patient's back against a ball propped on the wall
  - It is important to maintain neutral knee alignment, avoiding knee valgus or varus during squats

Sport-Specific Exercises

- Straight line running may begin at approximately 6 to 8 weeks if swelling is eliminated, gait is normalized, there is a negative posterior sag sign, patient is pain free with up and down steps and squatting exercises
  - Patients should run with brace on
  - Treadmill running is preferred initially to control the consistency of running surface and allow for immediate discontinuation of exercise if pain symptoms arise
  - Running can be advanced to outdoor running as endurance and strength allows
  - Distance may be progressed by 15% per week
    - If patient experiences symptoms of pain, swelling, or shifting in the knee the distance is reduced to the previous weeks distance for 2 weeks before advancing again
    - Repeat until goal running distance is achieved
- Patients can start to gradually return to sports activities around weeks 8 to 9 if they have met the following criteria:
  - Painless full ROM
  - No change in laxity
  - Adequate return of quadriceps strength has returned
  - At least 85% to 90% compared with that of contralateral normal leg
    - Measured by OKC and CKC knee extension exercises as well as compared by measurement around the thigh to compare muscle bulk versus the contralateral normal leg

Milestones for Progression to the Next Phase

- Full non-painful PROM by the end of week 6
- Improved lower extremity strength
  - Measured against the patients starting points when rehabilitation first began
- Single leg squat to 70° and held for 5 seconds
  - A 5-second hold allows for local fatigue of fast twitch muscle fibers and minimize contact forces around the knee.
- Flat ground running without asymmetry
- Negative posterior sag sign
  - Patient supine, knees flexed at 90°
  - Practitioner supports the legs and ankles and looks for the tibia to "sag" posteriorly
    - Posterior sag indicates PCL insufficiency
      - Positive sag sign could indicate a more severe PCL injury than first suspected and the patient may require repeat examination by the clinician/surgeon or further time spent on the exercises in the current phase
- Negative quads active test
  - Patient supine, knees flexed at 90°
  - Practitioner supports the patient's thigh to monitor muscle tone and stabilizes the foot with the other hand
  - Patient attempts to slide their foot down the table
    - A PCL deficient knee's tibia will move anteriorly
    - A normal knee's tibia will move minimally

Phase III (weeks 9 to 14)

Protection

- PCL support brace to prevent posterior tibia translation

Management of Pain and Swelling

- Similar to Phase II:
  - Vasopneumatic compression
  - Elevation
  - Compression wrap
  - Cryotherapy as needed
    - Should focus on icing after exercises for at least 20 minutes
  - Moist heat as needed

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Full passive range of motion

Soft Tissue Techniques

- Continue those from Phase I/II as needed

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Active range of motion (AROM) and active assisted range of motion (AAROM) continues toward full flexion, if not already achieved
- Stationary biking for ROM may begin once 105° of knee flexion is achieved
  - Seat height should be set so that the lower leg should have the knee slightly flexed
  - The foot should be placed slightly forward on the pedal (without toe clips) to minimize hamstring activity
  - Begin with zero resistance
  - Progress from 5 minutes to 20 minutes as strength permits

Other Therapeutic Exercises

- Total leg strength (TLS)
- Two sets of 8 to 12 repetitions for lower extremity strengthening
- Continue quadriceps sets
- Straight leg raises into hip flexion, extension, abduction
  - Resistance bands or weight should be added proximal to the knee joint as strength allows
- Open kinetic chain knee extension from 70° to 30° in sitting position
- Calf raises with the knee straight
  - Sets done slow and fast (each)
- Double leg squats to 90 degrees flexion
- Single leg squats (from 0° to 70°)
- Leg presses
  - Light weights (start off at 25% of body weight and maximize to 60% to 80%)
    - Start at 25% body weight and progress as tolerated with two sets of 8 to 12 repetitions for strengthening
    - Limit to 60% to 80% to prevent over exertion, improper form and potential injury
  - Maximum of 0° to 70° of knee flexion

Activation of Primary Muscles Involved

- Quadriceps
- Gluteals
- Gastrocnemius
- Hamstrings

Sensorimotor Exercises

- Weight shifts on involved limb
  - Three to five sets of 30 to 60 seconds for weight shift exercises
  - Eyes open and eyes closed
  - Progress to single leg stance, eyes open, on a firm surface
  - Increase difficulty by closing eyes and adding changing to an unstable surface (i.e., cushion, foam half-roller, air bladder, wobble board, or BOSU ball)

Open and Closed Kinetic Chain Exercises

- Two sets of 8 to 12 repetitions for OKC and CKC exercises
- OKC exercises
  - After 8 weeks, if posterior sag sign and posterior drawer are negative, patients may begin active hamstring strengthening
    - Hamstring strengthening should be initiated in CKC hamstring dominate exercises such as "good morning" exercises (Figure 33-32) and may progress to more isolated hamstring activation such as supine heel digs or eccentric rollouts on a Swiss ball (Figure 33-33)
    - As hamstring strength develops and no signs of increasing posterior instability appear, patients may progress to OKC hamstring strengthening against resistance

FIGURE 33-32. CKC hamstring exercises.

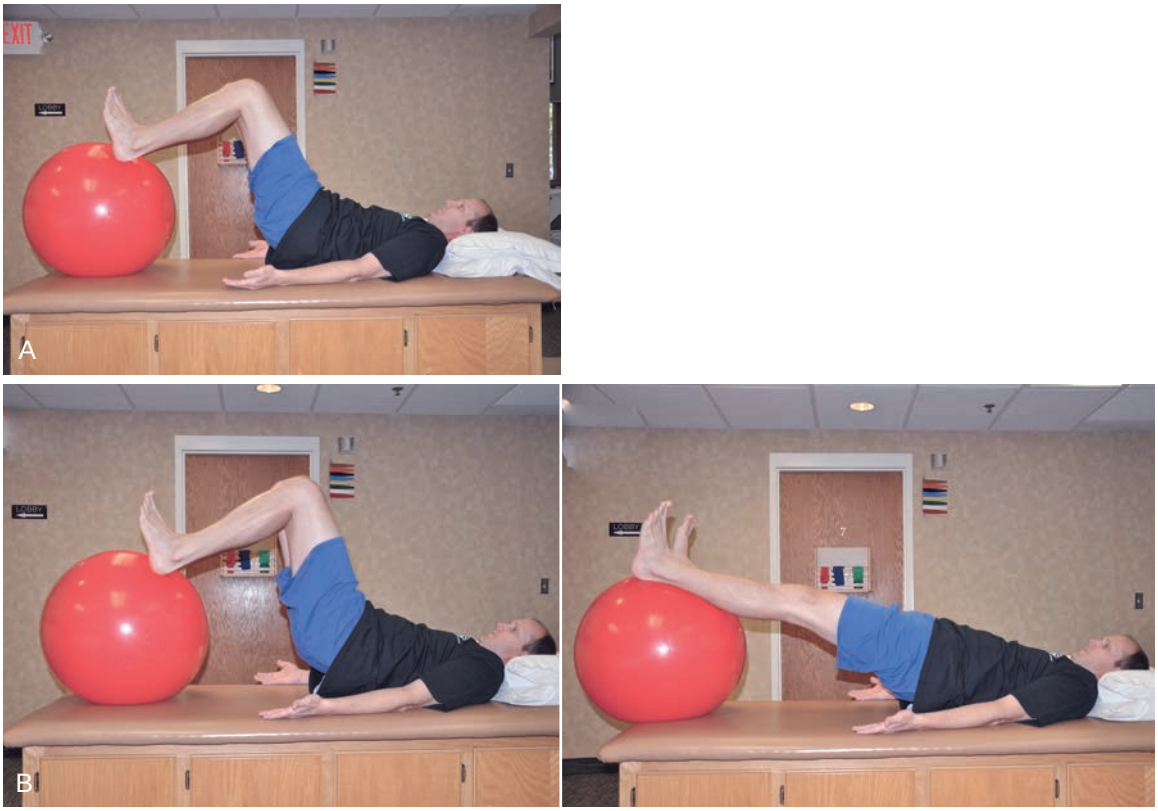

FIGURE 33-33. Supine heel digs (**A**) and eccentric rollouts (**B**) on a Swiss ball.

  - Patients should be directed to maintain neutral foot alignment throughout the ROM
- CKC exercises
  - Functional squats with resistance to 90° knee flexion
  - Single leg squat with dumbbell resistance to 70° knee flexion
  - Leg press to 90° flexion with two legs
  - Single leg eccentric leg press to 70° knee flexion
  - Standing single leg heel raises with dumbbell resistance
  - Lateral and backward walking with band resistance (Figure 33-34)

Techniques to Increase Muscle Strength, Power, and Endurance

- Stationary biking may be progressed as strength and endurance allow.
  - Low impact activities such as cycling may be increased as tolerated from 30 to 60 minutes.

FIGURE 33-34. Lateral (**A**) and backward (**B**) walking band resistance.

- Maintain approximately 80 rotations per minute as endurance allows.
- Begin straight ahead jogging after running progression completed.
  - Straight line running every other day for 30 minutes starting with 5 minutes fast walking and 1 minute jog repeated five times
  - Progress running by decreasing walk time by 1 minute and adding 1 minute to jog interval every other day

Neuromuscular Dynamic Stability Exercises

- Three to five sets of 30- to 60-second intervals for neuromuscular dynamic stability exercises
- Neuromuscular dynamic stability exercises are progressed on a continuum of difficulty depending on the patient's ability
- Exercises are advanced from double to single leg stance, from stable to unstable surfaces, and from predictable to unpredictable perturbations
- Perturbations may be manually applied or through the use of weighted balls

Plyometrics

- Deceleration and balance exercises should be mastered by now
  - Determined by ability to complete exercises while maintaining balance and proper posture/form
- Jump training may begin after 8 weeks
  - Training should emphasize controlled take off and landings without knee valgus or medial hip rotation
  - Jump training is cautiously progressed starting with two-legged jump ups onto a 6-inch box toward two-legged broad jumps and eventually single leg hop for distance
- Running at increasing speeds and sprints may begin at 9 to 10 weeks

Functional Exercises

- Functional step up exercises can be progressed to 12-inch step with dumbbell resistance
  - Step up exercises performed at two sets of 8 to 12 repetitions
  - Step ups should be performed forward, laterally, and with crossover step to further challenge the function of the lower extremity
- Jogging straight forward
  - Running may continue every other day for 30 minutes with no more than 10% increase in time per week
- Running progression
  - Marching → skipping → high knees → alternate leg bounding
    - Plyometric running progression can be performed at three sets of 30 seconds
    - Now include pivoting and cutting toward week 12

FIGURE 33-35. Grapevine step exercises. Begin with feet center, right foot steps over, then step behind the right foot with the left foot. Cross the left leg behind the right leg, and place the left foot behind and slightly to the right of the right foot. Left foot should be pointing toward the right heel, but not directly behind it. Take a step to the right with the right foot, bringing your feet together again. Continue the exercise by moving to the left.

Sport-Specific Exercises

- Sport-specific skill or agility training should begin
- Perform sport specific exercises three sets of 30-second intervals
  - 90 seconds rest between sets and 3 minutes rest between exercises
- Agility exercises may be initiated and progressed from straight line movements such as lateral shuffle, forward and backward sprints, and grapevine step exercises (Figure 33-35) to more advanced movements such as figure-eight running, short distance forward and backward sprint with 45 degree quick change in direction, and ladder drills
  - Grapevine is a step-over exercise seen in Figure 33-22
- Gradual return to sports practice
  - Build up to full return to practice

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- Full active ROM
- No evidence of instability or giving way
- Less than 80% difference in lower extremity strength
  - Measured by OKC and CKC knee extension exercises (quadriceps) as well as compared by measurement around the thigh to compare muscle bulk versus the contralateral normal leg
- Less than 85% difference in single leg hop for distance

Phase IV (weeks 15 to 20)

Protection

- Functional brace with sports

Management of Pain and Swelling

- Vasopneumatic compression
- Elevation
- Compression wrap
- Electrical stimulation
- Cryotherapy as needed

Techniques for Progressive Increase in Range of Motion

- Full AROM is expected

Manual Therapy Techniques

- Anterior tibial translation mobilizations and patellar mobilizations as needed to restore normal tibiofemoral contact points and decrease fixed posterior translation of the tibia if indicated.

Soft Tissue Techniques

- More aggressive tool assisted soft tissue mobilization may be required to elongate tissue and free up motion if normal ROM and flexibility around the joint is not yet achieved

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Contract/relax PNF stretching to quadriceps, gastrocnemius, hamstrings, hip flexors as indicated for normal symmetrical flexibility

Other Therapeutic Exercises

- Total leg strength (TLS)
  - Continue PREs for hip, knee, and ankle strength with added resistance
    - Two to three sets of 60% to 80%, one repetition, maximum three to four days per week
- Total body strength (TBS)
  - All upper body strengthening allowed in standing position
  - High level core exercises, Swiss ball exercises, and circuit training for upper and lower body conditioning
    - Two to three sets of 65% to 70% of one repetition maximum performed three to four days per week

Activation of Primary Muscles Involved

- Quadriceps, hamstrings, gastrocnemius

Open and Closed Kinetic Chain Exercises

- Two sets of 8 to 12 repetitions for OKC and CKC exercises
- OKC strengthening
  - Isolated hamstring strengthening, knee extension strengthening, hip strengthening all planes
- CKC strengthening
  - Resisted double leg squats to 90°
  - Resisted single leg squats to 70°
  - Resisted forward/reverse/lateral lunging

Techniques to Increase Muscle Strength, Power, and Endurance

- Resisted cycling at 80 to 100 RPMs, progressing as endurance allows
- Running program—increasing distance 15% per week or as symptoms allow

Neuromuscular Dynamic Stability Exercises

- Three to five sets of 30- to 60-second intervals for neuromuscular dynamic stability exercises
- Single leg stance windmill exercises (Figure 33-36)

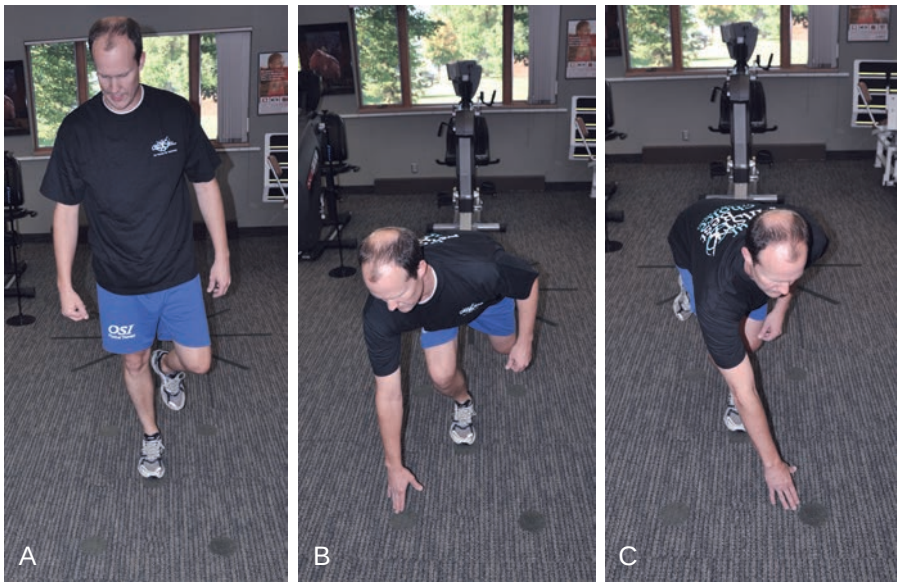

FIGURE 33-36. Single leg stance windmill exercise. Start (**A**), finishing to the right (**B**), and finishing to the left (**B**).

FIGURE 33-37. Power cleans progression

- Single leg stance on BOSU ball with medicine ball toss
- Single leg stance with manual perturbations
- Resisted walking with sport cord
- Lateral shuffle
- Grapevine running

Plyometrics

- Three sets of 30-second intervals for plyometric exercises
  - 90-second rest between sets and 3 minutes rest between exercise
- Two-leg broad jump
- One-leg broad jump
- One-leg triple jump
- One-leg crossover jump
- Two-leg drop jumps
- One-leg drop jumps
- High knee skipping

Sport-Specific Exercises

- Two sets of 8 to 12 repetitions for sport specific exercises
  - 30- to 60-second intervals for cutting and running activities
- Power cleans (Figure 33-37)
- Resisted running
- Figure-eight running
- 45° and 90° cutting
- Non-contact practice of sport

Guidelines to Progress to Advanced Sport-Specific Training and Conditioning

- Normal clinical examination—full active ROM, progressed to running
- Normal functional testing—hop tests, agility runs, gait testing
  - Completion of single leg hop for distance, triple cross over hop, and 6-meter hop testing performed at 90% of uninvolved limb (limb symmetry Index of 90%)
- No pain, swelling, or tenderness after training
- No increase in posterior laxity
  - Negative posterior sag sign
- No evidence/complaints of instability or giving way
- Quad strength in the injured leg is 85% to 90% or more than that of the uninjured leg
  - Measured by OKC and CKC knee extension exercises as well as compared by measurement around the thigh to compare muscle bulk versus the contralateral normal leg
- No signs of medial or patellofemoral joint space degeneration
- Greater than 90% functional strength achieved with return to sports testing
  - Completion of single leg hop for distance, triple cross over hop, and 6-meter hop testing performed at 90% of uninvolved limb (limb symmetry index of 90%)

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention

- Pain or degeneration of the medial or patellofemoral joint spaces
- Evidence/complaints of instability or giving way
  - Objectively grade instability with PCL stress radiographs
- Persistent pain with return to activity
- Inability to meet Phase I criteria
- Evidence of concomitant ligament, meniscal, or articular cartilage injury

Tips and Guidelines for Transitioning to Performance Enhancement

- Patients who have met the criteria for transition to advanced sport-specific performance enhancement training are progressed cautiously and monitored for recurrent symptoms throughout training.
  - Patients should not push training through pain or swelling.
- Both active and passive knee stability is challenged through sport-specific drills.
- Emphasis is placed on proper form and technique during all drills to reinforce proper lower extremity mechanics as well as protect from re-injury.
- Initial contact/tackling drills are initiated with use of pads and tackling dummies and progressed to live tackling drills.
- Continued stretching and maintenance of muscle strength are important to prevent re-injury.

Performance Enhancement and Beyond Rehabilitation: Training/ Trainer and Optimization of Athletic Performance

- Designed to bring athletic performance above and beyond entry level
- The goal is to return athletes to their sport at a performance level equal to or better than the level at the time of injury.
- Performance enhancement places extra focus on the injured limb and identifies other deficits that may have developed because of immobilization and deconditioning.

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Full AROM
- Normal quad strength
  - Measured by OKC and CKC knee extension exercises as well as compared by measurement around the thigh to compare muscle bulk versus the contralateral normal leg
- No evidence of instability or giving way
- Greater than 90% function on return to sports testing
  - Completion of single leg hop for distance, triple cross-over hop, and 6-meter hop testing performed at 90% of uninvolved limb (limb symmetry index of 90%)
- The athlete should understand the need for continued conditioning to prevent reinjury
- The athlete should be psychologically ready to return to sport and not be timid with the limb and fearful of reinjury
  - Test using the Tampa Bay Kinesophobia index or Fear Avoidance Belief Questionnaire (FABQ)

Evidence

Cross MJ, Powell JF: Long-term follow-up of posterior cruciate ligament rupture: A study of 116 cases. *Am J Sports Med* 12:292–297, 1984.

Case series that followed 116 PCL injuries, 55 were caused by sports injuries. An excellent or good result was obtained in 47 sports-injured patients. Found that patients with a posterior cruciate rupture can have a good result when treated conservatively (nonsurgically) if they maintain their strength and conditioning, especially concerning the quadriceps muscles. (Level IV evidence)

Escamilla RF, Fleisig GS, Zheng N, et al: Biomechanics of the knee during closed kinetic chain and open kinetic chain exercises. *Med Sci Sports Exerc* 30:556, 1998.

The study used 10 subjects who performed three repetitions of each exercise. Kinematic, kinetic, and electromyographic data were recorded using video cameras, force transducers, and EMG. Internal muscle forces and tension in the cruciate ligaments were estimated using a muscle model during CKC and OKC exercises. They found that tension in the PCL was highest in CKC exercises with knee flexion and that squats generated nearly two times as much hamstring activity compared to the leg presses and knee extensions. (Level IV evidence)

Harner CD, Xerogeanes JW, Livesay GA, et al: The human posterior cruciate ligament complex: an interdisciplinary study: Ligament morphology and biomechanical evaluation. *Am J Sports Med* 23:736–745, 1995.

This study used 14 human cadaver knees to examine the biomechanical properties of the femur-posterior cruciate ligament-tibia complex. The anterolateral bundle was found to have a significantly greater linear stiffness and ultimate load than both the posteromedial bundle and meniscofemoral ligaments. (Cadaveric study)

Ittivej K, Prompaet S, Rojanasthein S: Factors influencing the treatment of posterior cruciate ligament injury. *J Med Assoc Thai* 5:84–88, 2005.

Prospective study that followed 91 patients through a 1-year rehabilitation process following PCL injury. Patients were treated nonoperatively with a three-phase rehabilitation process. Authors found that the only factor correlating to failed nonsurgical rehabilitation was the degree of posterior laxity. Concluded that patients with greater than 10 mm of laxity should be treated surgically. (Level II evidence)

Jacobi M, Reischl N, Wahl P, et al: Acute isolated injury of the posterior cruciate ligament treated by a dynamic anterior drawer brace. *J Bone Joint Surg Br* 92-B:1381–1384, 2010.

Treated 21 patients with an isolated tear of the PCL for 4 months nonoperatively using a functional brace. Initial and follow-up stability was tested by Rolimeter arthrometry and radiography and clinical outcomes were measured using the Lysholm score, Tegner score, and International Knee Documentation Committee scoring system at 1 and 2 years. Found that the applied treatment produced a good or excellent functional result in all patients. Concluded the PCL has an intrinsic healing ability and will heal with less attenuation if the tibia is reduced to the proper anatomic position. (Level IV evidence)

Lutz GS, Palmitier RA, Chao YS: Comparison of tibiofemoral joint forces during open kinetic chain and closed kinetic chain exercises. *J Bone Joint Surg* 75A:732–739, 1993.

The study examined five healthy subjects to analyze forces at the tibiofemoral joint during open and closed-kinetic-chain exercises during maximum isometric contractions at 30°, 60°, and 90° of knee flexion. Electromyographic activity of the quadriceps and hamstrings, load and torque-cell data were recorded to calculate tibiofemoral shear and compression forces. Results indicated that CKC exercise produced significantly less posterior shear force at all angles when compared with the open kinetic chain extension exercise and that CKC exercise produced significantly greater compression forces and increased co-contraction of the muscles at the same angles that the OKC exercises produced the highest shear forces and lowest muscular co-contraction. (Level IV evidence)

Nadler S, Malanga G, DePrince M, et al: The relationship between lower extremity injury, low back pain, and hip muscle strength in male and female collegiate athletes. *Clin J Sport Med* 10:89–97, 2000.

Cohort study of 210 college athletes that measured average and maximum hip abduction and extension strength using a specially designed dynamometer anchoring station. Found a significant difference in side-to-side symmetry of maximum hip extension strength in female subjects who reported previous lower extremity injuries. This study supports the necessity of rehabbing and improving hip musculature strength to aid in return to sports after knee injuries. (Level III evidence)

Wilk KE, Escamilla RF, Fleisig GS, et al: A comparison of tibiofemoral joint forces and electromyographic activity during open and closed kinetic chain exercises. *Am J Sports Med* 24:518–527, 1996.

Study of 10 males performing four isotonic repetitions to investigate tibiofemoral compressive forces, anteroposterior shear forces, extension torque, and electromyographic activity of the quadriceps, hamstring, and gastrocnemius muscles during OKC knee extensions and CKC leg presses and squats. The findings showed significant differences in tibiofemoral forces and muscle activity between the CKC and OKC exercises. (Level IV evidence)

Multiple Choice Questions

QUESTION 1. During the initial phases of nonsurgical rehabilitation of a posterior cruciate ligament injury, it is important to avoid isolated activation of which muscle group to avoid stressing the injured ligament.

A. Gastrocnemius
B. Quadriceps
C. Hamstrings
D. Sartorius

QUESTION 2. Patients with a posterior cruciate ligament injury may begin plyometric training during which phase of rehabilitation, and only after mastering what other type of exercises?

A. Phase I, wall squats to 90°
B. Phase II, deceleration exercises
C. Phase III, straight forward running
D. Plyometrics are never allowed during rehabilitation of a PCL injury

QUESTION 3. When a patient who is undergoing active rehabilitation from a posterior cruciate ligament injury begins riding a stationary bike during Phase III, which of the following conditions should apply?

A. Stationary biking may begin once 105° of knee flexion is achieved
B. The seat height should be set so that the knee is slightly flexed
C. The feet should be placed slightly forward on the pedals
D. All of the above

QUESTION 4. When rehabilitating a patient with a combined PCL/PLC injury, which of the following is a strategic difference compared to the rehabilitation of a patient with an isolated PCL injury.

A. A patient with a combined PCL/PLC injury should initially be placed in a functional PCL brace.
B. The patient with a combined PCL/PLC injury does not require any posterior tibial support.
C. Patients with combined injuries do not need to avoid hamstring activating exercises during the initial phase of rehabilitation.
D. There are no differences in the rehabilitation of combined versus isolated injuries.

Answer Key

QUESTION 1. Correct answer: **C** With a damaged posterior cruciate ligament, it is important to avoid isolated activation of the hamstring muscles, which can increase posterior sheer forces on the damaged PCL until at least 6 weeks after the injury. The quadriceps are the single most important muscle to be strengthened and maintained during therapy because they are critical to joint stabilization. Strengthening of the gastrocnemius has no detrimental effect on a healing PCL, and the sartorius is not involved. (see Phase I)

QUESTION 2. Correct answer: **B** With an injured posterior cruciate ligament, patients cannot undertake plyometric exercises until Phase II at the earliest. Regardless of their progression, patients should be required to master deceleration exercises and proper landing technique before beginning plyometric exercises. Phase I does not include plyometrics, and patients should not be doing wall squats during Phase I. By Phase III patients should already have started plyometrics. (see Phase II)

QUESTION 3. Correct answer: **D** When patients begin riding the stationary bike during rehabilitation, they should have attained at least a 105° range of motion in the affected knee. To avoid activation of the hamstrings, the patient should ride the bike with the seat set to allow the knee to flex slightly and the feet slightly forward on the pedals. (see Phase III)

QUESTION 4. Correct answer: **A** The patient should be placed in a functional PCL brace. If a combined PLC and PCL injury is diagnosed the patient should be in a functional PCL brace to better support the posterior capsule. Patients with combined injuries still require posterior tibial support because they have a PCL deficiency. Patient with combined injuries still must avoid hamstring exercises early in rehabilitation to avoid posterior sheer forces on their damaged PCL. Grade III PCL/PLC injuries require surgery to repair or anatomically reconstruct the damaged structures, whereas partial tears to the PLC should be evaluated by a specialist to determine the proper course of action. (see Phase I)

POSTOPERATIVE REHABILITATION AFTER POSTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

Ernest M. Muntean, PT, MS, OCS, ATC, and Jon K. Sekiya, MD

Indications for Surgical Treatment

- Failure of nonoperative management including an aggressive quadriceps strengthening program
- Functional instability with sports or activities of daily living despite adequate rehabilitation
- PCL bony avulsion injuries may be fixed acutely before attempting non-operative management
- Multiple ligament injured knees (PCL along with ACL/lateral or medial sided injuries) are often fixed before an attempt at conservative management due to the significant instability and high rate of failure with non-operative management
- Isolated PCL injuries are often treated nonoperatively in both athletes and the non-athletic population owing to often satisfactory clinical outcomes in this injury pattern. However, a high index of suspicion should be held for concomitant posterolateral or posteromedial injuries[1-3] when significant posterior laxity exists greater than 10 mm. In addition, patients should be cautioned that a PCL-deficient knee is at risk for premature medial and patellofemoral compartment osteoarthritis despite reasonable functional stability

Brief Summary of Surgical Treatment

Major Surgical Steps

- Examine under anesthesia to document laxity pattern/compare with contralateral knee.
- Perform diagnostic arthroscopy to document all pathology, including a medial and lateral drive through sign to evaluate medial/lateral instability.
- Make a posteromedial arthroscopic portal to assist with tibial insertion site preparation.
- Perform tibial socket (for arthroscopic inlay) or transtibial tunnel for a PCL graft.
- Perform outside in or inside out double bundle PCL femoral tunnels in the anatomical insertion sites of the anterolateral (AL) and posteromedial (PM) bundles of the femoral PCL.
- Prepare a bifid Achilles allograft (preferred) or bifid autograft quadriceps tendon graft.
- Pass the graft and fix on tibial side.
- Reduce the knee joint and fix the femoral side.

Factors That May Affect Rehabilitation

Anesthetic

- Femoral nerve blocks can assist with postoperative pain relief. If doing a concomitant lateral-sided injury, avoid sciatic blocks until postoperative assessment can be made of peroneal nerve function.

Surgical

- Arthroscopic inlay PCL reconstruction can have the advantages of a minimally invasive arthroscopic approach with the advantages of the inlay technique that decreases the killer turn, which may have implications with postoperative range of motion.[4,5]
- Double bundle reconstructions have the advantage of a more anatomical restoration of PCL function.[6]
- Bi-cruciate PCL and ACL injuries are a more unstable injury pattern and thus need more protection during postoperative rehabilitation.
- Collateral ligament reconstruction (medial- or lateral-sided injuries) create an even more unstable pattern in which varus and valgus forces must be protected postoperatively.[7]

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- The clinician should understand the surgical procedure performed.
- The clinician should understand the anatomy and function of the PCL in providing knee tri-plane stability.
- The clinician should understand basic tissue healing.
- The clinician must understand the postoperative goals and precautions to provide for safe and effective progression to maximize athlete outcomes.

Phase I (days 0 to 14): Immediate Postoperative Period[1]

Goals

- Protect the PCL graft.
- Decrease pain and swelling.
- Improve quadriceps neuromuscular control.
- Increase ROM to 0° to 90°.
- Instruct in daily independent home exercise program (HEP).

Protection

- Knee is kept in ROM brace locked in extension at all times except for shower (including sleep, exercises, *no exceptions*).

[1]*Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

- Axillary crutches used to initiate 30% PWB of involved lower extremity with brace locked in extension.

Management of Pain and Swelling

- Treatment for pain
  - Oral pain medications
  - Continuous cryotherapy
  - Electrotherapy—TENS, interferential, pre-modulated
- Treatment for swelling
  - Elevation of lower extremity above the heart
    - Compression
    - Stockings
    - ACE wrap
  - Compliance with weightbearing instructions

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Precaution: Limit ROM to 0° to 90°
- Knee flexion: ROM should be passive to avoid isolated hamstring activation to prevent posterior tibial translation of the tibia on the femur, which may produce excessive tension of the graft.
- Patellar mobilizations

Soft Tissue Techniques

- Effleurage for swelling reduction.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Passive stretching of the calf, hamstring, and hip flexor bilaterally
- Continuous passive motion for at least 1 hour per day at 0° to 90°.

Other Therapeutic Exercises

- Athletes are encouraged to participate in upper body cardiovascular conditioning exercises when able to do so comfortably and safely as determined by the clinician.
  - Upper body ergometer (UBE)

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Quadriceps re-education with use of NMES
  - High-volt
  - Russian
- Quadriceps setting exercises
- Biofeedback

Clinical Pearl

To assist with volitional activation of the quadriceps muscle group, have the athlete contract this musculature while the e-stim is in the on-cycle while relaxing during the off-cycle. Progress to an active straight leg raise (SLR) during the on-cycle once the athlete demonstrates improved quad control.

Open and Closed Kinetic Chain Exercises

- Four-way SLR
  - Abduction and adduction are contraindicated with athletes who have had a concurrent ACL or collateral reconstruction/repair.
- Resisted ankle pumps.

Milestones for Progression to the Next Phase

- Full knee extension ROM
- Improving quadriceps control
- Decreasing swelling
- Patient compliance with daily HEP, PWB, and brace/crutch use

TIMELINE 33-2: **Postoperative Rehabilitation After Posterior Cruciate Ligament Injury**

PHASE I (postoperative weeks 0 to 4)	PHASE II (postoperative weeks 4 to 8)	PHASE III (postoperative weeks 8 to 16)
• Knee brace locked in full extension • No active hamstring contraction for heel slides • 30% PWB with axillary crutches in brace • PT modalities for pain/swelling control and quad re-education • PROM—0–90° • TBS/TAS/TLS activities as recommended and tolerated • OKC—band calf pumps • OKC—SLRs	• Continue knee brace locked in extension • No active hamstring contraction for heel slides • Progress ambulation to FWB in brace • PT modalities for pain/swelling control and quad re-education • PROM to full • TBS/TAS/TLS activities as recommended and tolerated • Initiate retro-biking at week 6 • Initiate balance/proprioceptive training with weight shifting exercise • OKC—band calf pumps • OKC—SLR for hip in standing	• Knee brace unlocked for ambulation • Initiate active assisted heel slides • DC crutches when gait in normalized • PT modalities as needed for pain/swelling and quad re-education • AROM—full • Initiate hamstring setting exercise • TBS/TAS/TLS activities as recommended and tolerated • Progress balance with upper extremity reaches • OKC—long arc quad exercise 45°–90° without resistance • CKC—mini squats with <45° of knee flexion • CKC—calf raises • CKC—step ups/downs • Neuromuscular—PWB BAPS level 1, wobbleboard

Phase II (postoperative weeks 4 to 8)

Goals

- Increase ROM to full
- Decrease pain and swelling
- Normalize quadriceps control
- Return to FWB ambulation
- Increase lower extremity strength

Protection

- Continue use of brace without ROM restrictions.
- Wean to a single crutch in the opposite upper extremity at four weeks if athlete demonstrates:
  - Full knee extension ROM
  - Normal quadriceps control: Athlete able to perform a SLR without an extension lag

Management of Pain and Swelling

- Treatment for pain
  - Oral pain medications
  - Cryotherapy
  - Electrotherapy: TENS, interferential, pre-modulated
- Treatment for swelling
  - Elevation of lower extremity above the heart
  - Compression:
    - Stockings
    - ACE wrap

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- ROM can progress to full.
- Knee flexion ROM should be passive to avoid isolated hamstring activation to prevent posterior tibial translation of the tibia on the femur, which may produce excessive tension of the graft.
- Patellar mobilizations.

Soft Tissue Techniques

- Effleurage for swelling reduction.
- Cross-friction massage to mobilize scar tissue.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Progress multi-plane stretching of the calf, hamstring, and hip flexor bilaterally to standing, such as true stretch.
- Stationary cycling can be initiated at 6 weeks
  - No resistance
  - Seat elevated to limit knee flexion ROM
  - *No toe straps* to limit hamstring activation

Clinical Pearl

> Have the athlete perform retro- or backward cycling initially. The change in direction will facilitate more quadriceps activation while limiting hamstring activation.

Other Therapeutic Exercises

- Continue use of upper body ergometer for cardiovascular conditioning.
- Initiate partial Turkish get-ups with kettlebell for core strengthening (Figure 33-38).

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Continue quad re-education with NMES
- Quadriceps sets

TIMELINE 33-2: Postoperative Rehabilitation After Posterior Cruciate Ligament Injury (Continued)

PHASE IV (postoperative weeks 16 to 20)	PHASE V (postoperative weeks 20 to 26)	PHASE VI (postoperative weeks 26 to 32)
• TBS/TAS/TLS activities as recommended and tolerated • PT modalities as needed for pain/swelling • CKC—leg press 0°–60° • CKC—hip abd/add machine • CKC—multi-plane lunges • CKC—hamstring curls • Neuromuscular—PWB BAPS level 2, wobbleboard, balance reach exercises • Initiate light throwing activities • Leg press test >75%	• TBS/TAS/TLS activities as recommended and tolerated • CKC—leg press 0°–90° • CKC—mini squats on unstable/unlevel surface • CKC—multi-plane lunges with dumbbells • CKC—step downs with progressive height • Neuromuscular—add resistance to balance reach exercise • Jump rope training • Initiate slow jogging	• TBS/TAS/TLS activities as recommended and tolerated • CKC—progression of resistances • Plyometrics—box jump • Progress jogging to running • Agilities—initiate cariocas, cutting, and pivoting • Initiate sports specific activities

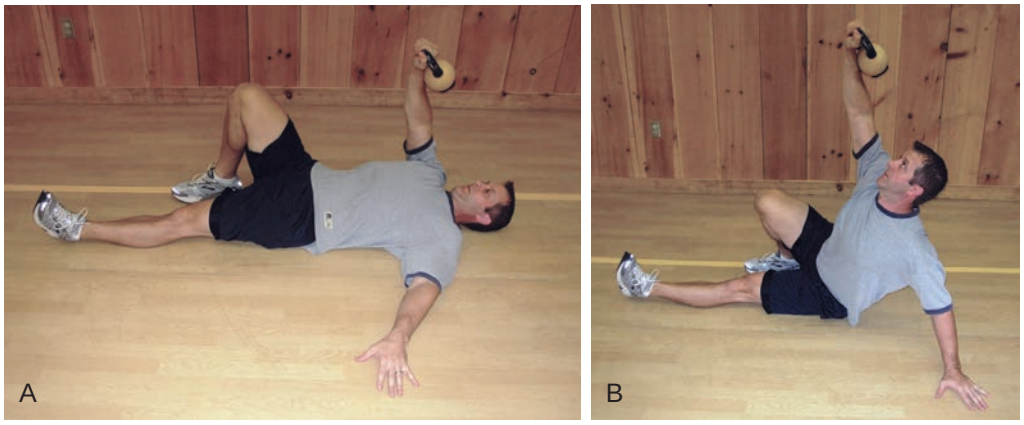

FIGURE 33-38. Partial Turkish get-up with kettlebell.

Sensorimotor Exercises

- Initiate lower body lateral weight shifting exercises—forward, retro, and lateral.[8]

Open and Closed Kinetic Chain Exercises

- Continue four-way straight leg raises.
- Four-way standing hip exercise
- Full long arc quads exercise without resistance

Techniques to Increase Muscle Strength, Power, and Endurance

- Initiate upper body strengthening.

Milestones for Progression to the Next Phase

- Normalized quadriceps control
- Minimal to no swelling
- Full knee extension ROM

Phase III (postoperative weeks 8 to 16)

Goals

- Progression of lower body strengthening
- FWB ambulation in brace without compensations
- No swelling
- Improved balance and proprioception

Protection

- Knee brace can be unlocked at all times
- Must remain in place at ALL times, including sleep and exercises
- Discontinue use of crutches once the athlete has normal quadriceps control, minimal to no swelling, full knee extension ROM, and minimal to no gait deviations

Management of Pain and Swelling

- Treatment for pain
  - Oral pain medications
  - Cryotherapy
  - Electrotherapy: TENS, interferential, pre-modulated
- Treatment for swelling
  - Continue ice, elevation, and compression

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Progress multi-plane stretching of the calf, hamstring, and hip flexor bilaterally to standing, for example, True Stretch (Figure 33-39).

Other Therapeutic Exercises

- Athlete may begin to use a stationary bike at this time without the use of toe straps.

FIGURE 33-39. True stretch calf/hip flexor stretch.

FIGURE 33-40. Rope undulation training—alternating arms.

- Progress cardiovascular conditioning with use of treadmill, Elliptical trainer, stationary bike, or stair climber.
- Initiate rope undulation training (Figure 33-40).

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Initiate active assisted heel slides.
- Initiate hamstring sets in the long seated position.
- Retro-exercises for progression of quadriceps/calf activation and strengthening. Examples are retro-step ups, retro stair climber, and treadmill.

Sensorimotor Exercises

- Balance reach exercises in multiple planes. Athlete balances on the involved extremity and reaches with the uninvolved extremity to predetermined directions at the treating clinician's discretion.[9]
- Initiate PWB BAPS at level 1 performed while standing.

Clinical Pearl

Have the athlete perform the BAPS exercise by having him/her rotate the board one revolution clockwise followed by one revolution counterclockwise for completing one repetition. This minimizes the influence of momentum to assist the athlete.

Open and Closed Kinetic Chain Exercises

- Long arc quad (LAQ) exercise without resistance limited to 45° to 90° arc of motion.
- Weightbearing exercises including: standing calf raises, mini squats not to exceed 45° of knee flexion, and stepups/downs.
- Initiate CKC exercises:
  - Calf raises. Initially with bodyweight only and progressively adding resistance with dumbbells or calf raise machine.
  - Mini squats limited to 45° of knee flexion.

Clinical Pearl

Once the athlete is comfortable performing the mini squat exercise, then add the use of dumbbells to perform overhead presses to increase upper body and core strength. These presses can be performed with both arms together or in an alternating fashion.

Techniques to Increase Muscle Strength, Power, and Endurance

- Leg press machine. Begin with both extremities and use low resistance and high repetitions progressing to higher resistances and also to involved extremity only. Knee flexion angle not to exceed 45°.[10]

Neuromuscular Dynamic Stability Exercises

- Balance reach with upper extremity reaches. Patient balances on the involved lower extremity, reaching with both upper extremities anteriorly and/or overhead posteriorly and vertical heights (e.g., shoulder, knee) (Figure 33-41).

Milestones for Progression to the Next Phase

- Full ROM
- Normal gait pattern
- No swelling
- Excellent quad control

FIGURE 33-41. Single leg balance, bilateral upper extremity anterior to waist reach.

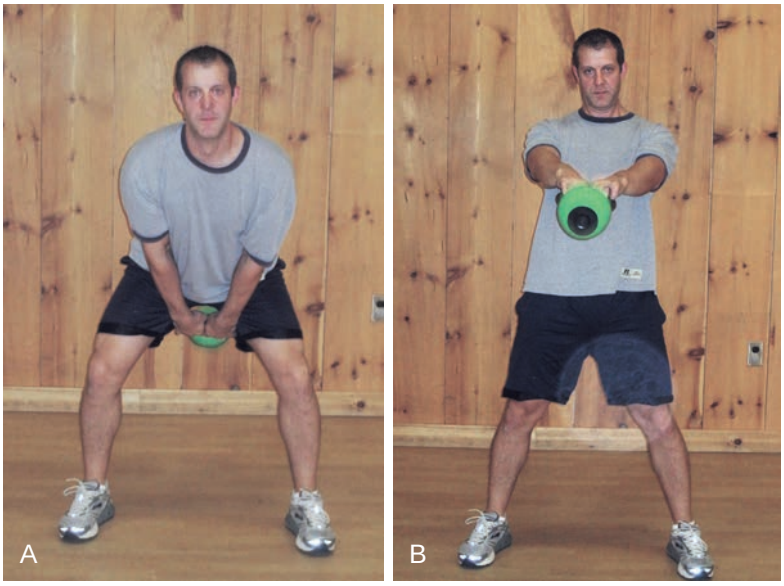

FIGURE 33-42. Kettlebell swing with both arms.

Phase IV (postoperative weeks 16 to 20)

Goals

- Progress strengthening in 0° to 60° ROM.
- Discontinue use of protective brace.
- Progress cardiovascular conditioning with use of lower body.
- Successfully pass a leg press test (greater than 75% of uninvolved extremity).

Management of Pain and Swelling

- Continue ice, elevation, and compression as necessary.

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Continue multi-plane stretching of the calf, hamstring, and hip flexor bilaterally to standing, for example, true stretch.

Other Therapeutic Exercises

- Initiate fast walking on the treadmill.
- Pool exercises to progress conditioning. Kicks should be kept in the sagittal plane to protect the reconstructed graft, therefore avoid frog kicking motion for breast stroke.
- Initiate kettlebell swings (Figure 33-42).
- Progression of rope undulation training:
  - Performing squats in symmetrical stance
  - Performing squats in a tandem stance
  - Single leg squat

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Initiate isolated, resisted hamstring curls with low resistance and high repetitions.
  - Seated
  - Prone

Sensorimotor Exercises

- Initiate balance reach exercise with the opposite lower extremity (Figure 33-43).

Open and Closed Kinetic Chain Exercises

- Mini squats can be progressed to single leg. Additionally dumbbells can be used for upper body matrix presses (Figure 33-44).[11]

FIGURE 33-43. Balance opposite lower extremity anterior reach.

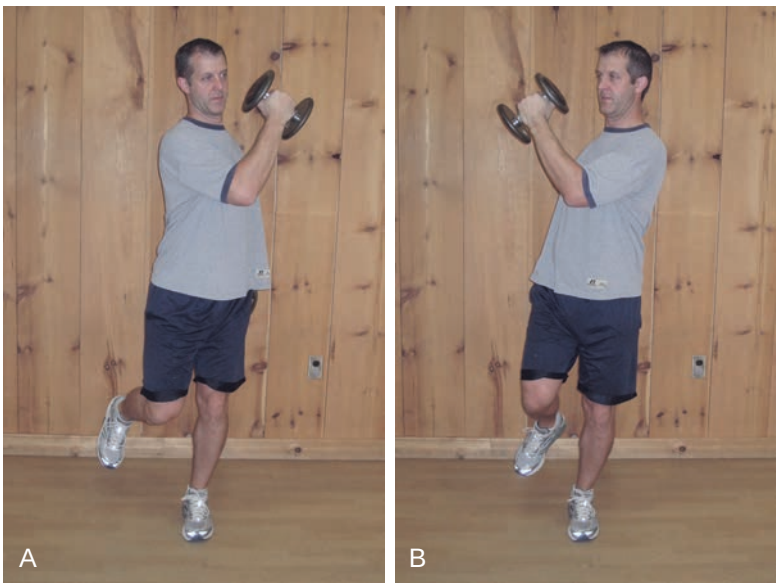

FIGURE 33-44. Single leg squat with alternating dumbbell uppercuts.

Techniques to Increase Muscle Strength, Power, and Endurance

- Progression of leg press resistance. Available knee flexion angle can be safely progressed to 60°.
- Initiate seated hip abduction and adduction machines.

Neuromuscular Dynamic Stability Exercises

- Progress balance reach exercises with the upper extremities to include added resistance from bands, dumbbells, Bodyblade, and so on.
- Progress BAPS exercises to level 2. Additionally progress weightbearing to full as patient is able to safely perform this exercise.

Functional Exercises

- Initiate involved lower extremity sagittal plane lunges. Athlete may need upper body support initially for safety and progressed to unsupported when safe.

Clinical Pearl

Depth of lunges should be self-selected by the athlete initially to avoid undesired compensatory patterns. The depth of the lunge should be progressed to not more than 60° of knee flexion once the athlete can safely perform without compensations in the early ranges.

Sport-Specific Exercises

- Throwing can be initiated for throwing athletes. This should be kept to relatively shorter distances for the primary purpose of restoring normal throwing mechanics.

Milestones for Progression to the Next Phase

- Leg press test: Athlete must successfully complete at least 75% repetitions of involved extremity versus the uninvolved extremity at 100% bodyweight.

Phase V (postoperative weeks 20 to 26)

Goals

- Initiate slow jogging
- Progress lower body strengthening
- Progress agility exercises

Management of Pain and Swelling

- Continue ice, elevation, and compression.

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Continue multi-plane stretching of the calf, hamstring, and hip flexor bilaterally to standing, for example, true stretch.

Other Therapeutic Exercises

- Progress intensity and frequency of aerobic, kettlebell, and rope undulation cardiovascular training.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Progress resisted hamstring curls with progressively increased resistance and decreased repetitions.

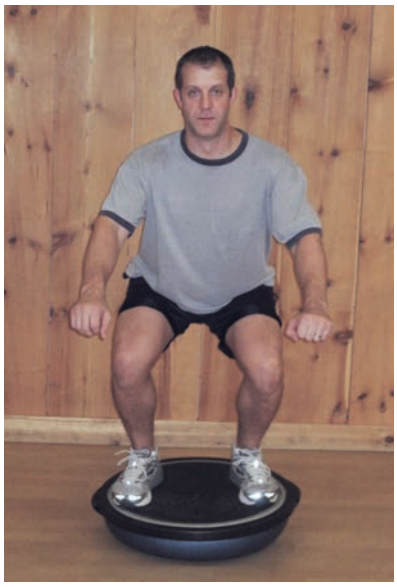

FIGURE 33-45. Mini squats performed on a BOSU.

Sensorimotor Exercises

- Progress balance lower extremity reach exercises with use of dumbbells, Bodyblade, and so on.

Open and Closed Kinetic Chain Exercises

- Progress mini squats by moving to an unstable or unleveled surface (Figure 33-45).

Techniques to Increase Muscle Strength, Power, and Endurance

- Progress resistance of leg press exercises.

Neuromuscular Dynamic Stability Exercises

- Progress exercises from Phase IV
- Initiate standard jump rope training exercises

Functional Exercises

- Progress lunges to include both frontal and transverse planes. Dumbbells may be used with the lunge exercise to facilitate upper body and core strengthening (Figure 33-46).

Sport-Specific Exercises

- Initiate light jogging activities on level ground or treadmill. Cutting, jumping, or pivoting should be avoided.

Milestones for Progression to the Next Phase

- Athlete should be able to run short distances without compensations.

Phase VI (postoperative 26 to 32)

Goals

- Initiate plyometric training exercises
- Initiate sports specific activities
- Progress lower body strengthening

Management of Pain and Swelling

- Continue ice, elevation, and compression.

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Continue multi-plane stretching of the calf, hamstring, and hip flexor bilaterally to standing, for example, true stretch.

Other Therapeutic Exercises

- Progress Phase V activities.

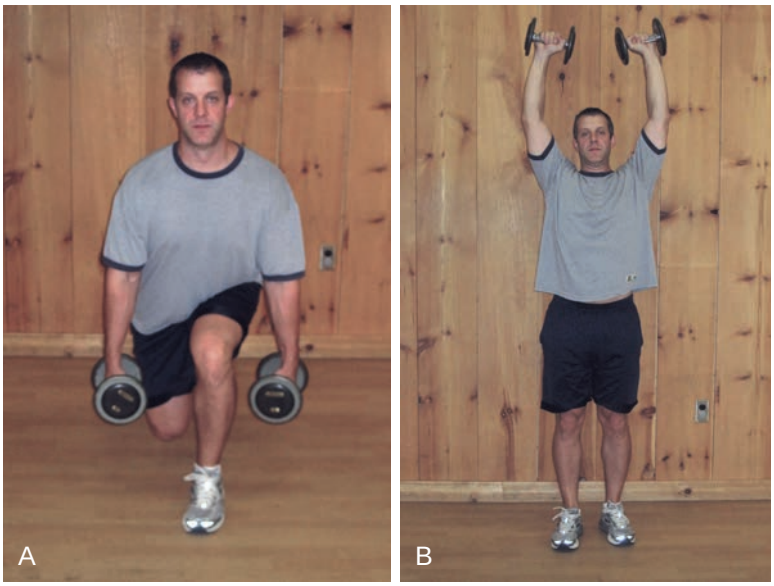

FIGURE 33-46. Lunge with dumbbell reach and press.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Progress resisted hamstring curls with increasing resistances.

Sensorimotor Exercises

- Progress balance lower extremity reach exercises.

Open and Closed Kinetic Chain Exercises

- Progress mini squats by moving to an unstable or unleveled surface.

Techniques to Increase Muscle Strength, Power, and Endurance

- Progress resistance of leg press exercises.

Neuromuscular Dynamic Stability Exercises

- Progress exercises from Phase V.
- Progress jump rope training to line jumps: anterior/posterior and lateral.

Plyometrics

- Initiate plyometric jumping activities. It is important to begin with light jumping from a low height. Careful observation is required to assess for asymmetry of movement and for compensations. When the athlete can safely perform these activities, then it is appropriate to progress the height and the intensity of the jumping.

Functional Exercises

- Progress lunges to include both frontal and transverse planes. Dumbbells may be used with the lunge exercise to facilitate upper body and core strengthening.

Sport-Specific Exercises

- Progress speed of running activities.
- Initiate multi-plane agility training (e.g., retro running, cutting, crossovers, cariocas)

Milestones for Progression to the Next Phase

- Minimum of 90% strength with involved lower extremity as compared with the uninvolved lower extremity with the leg press test.
- Sprinting drills without compensations.
- Ability to perform agilities without compensations.

Criteria for Return to Sport

General

- Quadriceps and hamstring strength at least 90% of uninvolved lower extremity.
- One-leg hop test and vertical jump at least 90% of uninvolved lower extremity.
- Jog, full speed run, shuttle run, and figure-eight running without compensations.
- Squat and rise from a full squat without pain or compensations.
- No swelling or quadriceps atrophy.
- Satisfactory clinical examination.

Sport-Specific

- It is important to identify athletes who may satisfy the criteria for return to support, however demonstrate asymmetries or adverse compensations while performing sport-specific drills. These athletes may need further neuromuscular training to facilitate safe, effective participation.
- The medical staff (MD, PT, ATC) must properly evaluate the athlete in the context of his or her sport as well as the specific position within that sport. This needs to be done on an individual basis because it is difficult to generalize these physical demands among a diverse athletic population. Sport-specific demands vary because of environment (turf, grass, other), contact versus noncontact (e.g., opponent, equipment), and physiological factors (e.g., slow endurance–type activity, ballistic activity).
- The clinician should understand that this protocol assumes that there has been no surgical reconstruction of the other major stabilizing structures of the knee, such as anterior cruciate ligament (ACL), lateral collateral ligament (LCL), or medial collateral ligament (MCL). Further protective time frames and precautions are necessary for optimal functional outcomes of rehabilitation.
  - PCL + ACL reconstruction: Modification of time frames with additional precautions
    - Phase IV is extended to 4 to 6 months.
    - Phase V is extended to 6 to 9 months.
    - Phase VI is extended to 9 to 12 months.
    - Protective brace is used for the first 5 months of rehabilitation.
  - PCL + collateral (MCL and/or LCL) reconstruction: Modification of time frames with additional precautions
    - Phases are the same as PCL + ACL time frames.
    - Protective brace is utilized for the first 6 months of rehabilitation.
    - Frontal and transverse plane exercises not initiated until Phase V. This is delayed for the purpose of protecting the collateral ligament reconstruction.

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Continue the previously outlined total arm and body conditioning activities.

Evidence

Bowman K, Sekiya JK: Anatomy and biomechanics of the posterior cruciate ligament, medial and lateral sides of the knee. *Sports Med Arthrosc Rev* 18(4):222–229, 2010.

Article discusses the function of the PCL, medial and lateral sides of the knee in providing posterior as well as valgus, varus, and rotational stability. (Level of evidence = N/A)

Earl JE, Hertel J: Lower-extremity muscle activation during the star excursion balance tests. *J Sport Rehabil* 10:93–104, 2001.

Quadriceps training via the Star Excursion Balance Tests with an anterior reach facilitated the greatest VMO and VL activity versus the hamstring muscle group. (Level IV evidence)

Lephart SM, Pincivero DM, Giraldo JL, et al: The role of proprioception in the management and rehabilitation of athletic injuries. *Am J Sports Med* 25(1):130–137, 1997.

This article examines the diminished effect of joint proprioception resulting from ligamentous injury and surgical interventions. The authors state that rehabilitation programs should include a proprioceptive component to promote functional joint stability. (Level V evidence)

Powers CM: The influence of abnormal hip mechanics on knee injury: A biomechanical perspective. *JOSPT* 40(2):42–51, 2010.

The author presents a biomechanical argument to include pelvic and hip stability, as well as dynamic hip joint control into the rehabilitation of knee injuries. (Level V evidence)

Salata MJ, Sekiya JK: Arthroscopic PCL tibial inlay: Surgical technique that may influence rehabilitation. *Sports Health* 3:52–58, 2011.

This article suggests that there are unique features of an arthroscopic, double bundle PCL reconstruction that allow a more aggressive postoperative rehabilitation approach. (Level V evidence)

Sekiya JK, Haemmerle MJ, Stabile KJ, et al: Biomechanical analysis of a combined double bundle posterior cruciate ligament and posterolateral corner knee reconstruction. *Am J Sports Med* 33(3):360–369, 2005.

You need to address the posterolateral corner if injured when reconstructing the PCL to restore normal knee kinematics and stability. (Level of evidence = N/A)

Sekiya JK, Whiddon DR, Zehms CT, et al: A clinically relevant assessment of PCL and posterolateral corner injuries: Evaluation of isolated and combined deficiency. *J Bone Joint Surg Am* 90(8):1621–1627, 2008.

The posterolateral corner contributes to significant posterior stability in the PCL deficient knee and should be suspected in patients with significant posterior laxity. A high index of suspicion should always be present when examining PCL injuries. (Level of evidence = N/A)

Tibor LM, Marchant MH, Sekiya JK, et al: Management of medial sided knee injuries, Part 2: Posteriomedial corner. *Am J Sports Med* 39:1332–1340, 2011.

This article reviews the relevant literature on the PMC, discusses reasons for selective operative management, and illustrates reconstructive strategies for PMC injuries occurring as part of a medial-sided or multi-ligament injury to the knee. (Level of evidence = N/A)

Whiddon DR, Zehms CT, Sekiya JK, et al: Comparisons of a double bundle arthroscopic inlay and open inlay posterior cruciate ligament reconstruction using clinically relevant tools: A cadaveric study. *Arthroscopy* 24(4):472–480, 2008.

The double bundle inlay PCL reconstruction provides comparable stability to the open inlay technique. (Level of evidence = N/A)

Whiddon DR, Zehms CT, Sekiya JK, et al: Double compared with single-bundle open inlay posterior cruciate ligament reconstruction in a cadaver model. *J Bone Joint Surg Am* 90:1820–1829, 2008.

This cadaver study demonstrates that the double-bundle surgical reconstruction offers measurable benefits in terms of rotational stability and posterior translation of an untreated posterolateral corner injury. (Level of evidence = N/A)

Wilk KE, Escamilla RF, Fleisig GS, et al: A comparison of tibiofemoral joint forces and electromyographic activity during open and closed kinetic chain exercises. *Am J Sports Med* 24(4):518–527, 1996.

This study demonstrated that the posterior directed shear force of the knee was greatest between 85° and 105° of knee flexion in a closed chain environment. (Level IV evidence)

Multiple Choice Questions

QUESTION 1. Immediately postoperatively, active contraction of the _____ must be avoided to prevent _____ translation of the tibia on the femur, which may produce excessive tensioning of the graft.

A. Quadriceps; anterior
B. Hamstrings; anterior
C. Quadriceps; posterior
D. Hamstrings; posterior

QUESTION 2. Which of these exercises would be contraindicated for an athlete who had a surgical reconstruction of both his PCL and LCL immediately postoperatively?

A. SLR—flexion
B. SLR—abduction
C. SLR—extension
D. All the above

QUESTION 3. When is it safe to initiate the seated hip abduction machine for an athlete with a PCL/LCL reconstruction?

A. Month 6–8
B. Month 5–6
C. Month 4–5
D. Month 2–4

QUESTION 4. Light jogging is to initiate during which time period?

A. Month 2–4
B. Month 4–5
C. Month 5–6
D. Month 6–8

QUESTION 5. During the first month postoperatively, the knee brace can be unlocked for:

A. Showering
B. Driving
C. Riding the stationary bike
D. Walking

Answer Key

QUESTION 1. Correct answer: **D** (see Month 0 to 1)

QUESTION 2. Correct answer: **B** (see Month 0 to 1)

QUESTION 3. Correct answer: **B** (see Month 5 to 6)

QUESTION 4. Correct answer: **C** (see Month 5 to 6)

QUESTION 5. Correct answer: **A** (see Month 0 to 1)

BEYOND BASIC REHABILITATION: RETURN TO FOOTBALL AFTER POSTERIOR CRUCIATE LIGAMENT INJURY

Robert F. LaPrade, MD, PhD, Casey M. Pierce, MD, and Scott Wilkins, DPT, OCS

Introduction

ASPECTS OF FOOTBALL THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- High impact nature
- Variability of playing position
- Relatively limited number of season games

- PCL injuries are most often the result of trauma and high-impact sports injuries such as those occurring in football
  - Injuries to the knee are 13 times more likely during a season game compared with a practice.
- The most common athletic-related injury is falling onto a flexed knee with the ankle plantarflexed.
  - This injury may be seen in a blocking lineman who slips and falls directly onto a flexed knee.
- A direct blow to the anterior tibia with the knee in a flexed position is the second most common mechanism.
  - May occur from being tackled while playing positions such as wide receiver, running back, or quarterback
- The injury may be more common than we think because an average of four to six NFL players in each draft class (of approximately 200 players) are found to have chronically PCL-deficient knees
  - Incidence around 2% for isolated injuries and slightly higher for combined injuries

Literature

- A study by Parolie and Bergfeld[1] investigated patients who were treated conservatively for PCL injuries, including 12 NFL football players.
  - 67% returned to play in the NFL
  - Quadriceps strength was critical to obtaining good outcomes

Phase I: Advanced Strength and Conditioning Programs

Periodization

- In Phase I, a linear periodization model is used to progress the athlete through three areas of training
  - Training focus changes from anatomical adaptations and endurance enhancement to muscle hypertrophy

and eventually progresses to strength and power enhancement
- Phase I linear periodization consists of short weekly microcycles with exercise progression occurring at weekly intervals.

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum: Training in Phase I is progressed on a continuum via increases in volume of exercise and/or intensity as well as reduction of rest intervals.
- Flexibility/joint mobility for joint stability: Daily stretching for shortened muscles and normalized joint mobility is performed throughout Phase I and can be incorporated into daily cool down regimen.
  - Joint mobilization may be included to restore normal tibiofemoral contact points in a PCL-injured knee.
- Training with optimum posture. Optimum posture is emphasized throughout the exercise routine to reduce risk of injury and limit compensation strategies for the involved limb.
  - All exercises must be performed with optimum posture at current intensity and volume before progression is allowed.
  - Substitutions such as excessive forward lean during squatting activities will over-recruit the hamstrings and place increased stress on the healing ligament (Figure 33-47)
- Sensorimotor and balance training is incorporated into rest periods to further train the proprioception system and to maximize use of rest intervals.
- Core training is maintained and progressed throughout Phase I with emphasis on neutral spine postures and maximization of both lower and upper extremity movement and strength around a neutral spine posture.
  - Performed daily and avoids use of the involved limb for bracing during the acute healing phase
- Cardiorespiratory training is advanced not only through the endurance phase of training, but is also included as a daily exercise throughout all phases.
  - Cardiovascular exercise is used to maintain aerobic capacity during rehabilitation and minimize the effects of detraining following injury.

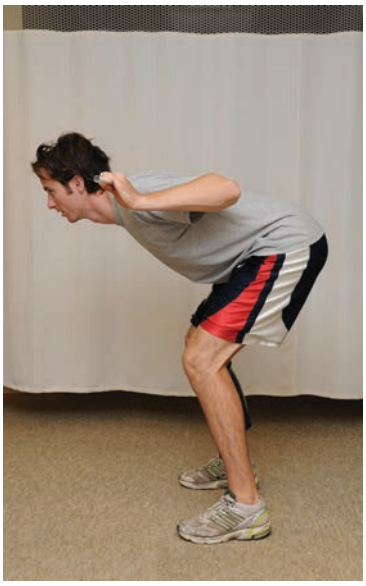

FIGURE 33-47. Improper forward lean during squats stressing the hamstring.

Training Principles Used in the Design of the Program

- The principle of progression is used to advance Phase I exercises through a linear advancement of intensity, volume, and reduction of rest intervals.
- The principle of overload is used to improve endurance, stimulate hypertrophy, and ultimately increase strength and power output of muscles.

Application of Acute Training Variables

- Repetitions: 10 to 14 repetitions in the endurance phase, 8 to 12 repetitions in the hypertrophy phase, and four to six repetitions in the power/strength phase
- Sets: three to four each
- Rest interval: 30 seconds between exercises and 60 seconds between sets initially
- Intensity: low intensity with high repetitions in endurance phase and increasing linearly as repetitions decrease through the hypertrophy and into the power phase

TIMELINE 33-3: **Return to Football After Posterior Cruciate Ligament Injury**

PHASE I (weeks 1 to 3)	PHASE II (weeks 4 to 9)	PHASE III (weeks 10 to 12)
• PCL Jack brace • PT modalities as needed for pain control • Stretching and ROM exercises • TLS-OKC knee extension, four-plane straight-leg raise, calf raises, leg press, lunges, two- and one-leg squats, and resisted walking/running • TBS-Pull ups, seated rows, neutral spine core exercises in prone and supine, treadmill running • Core strengthening/stabilization exercises • Balance and proprioception exercises	• PCL Jack brace • PT modalities as needed for pain control • TLS: resisted lateral and backward band walking, band resisted hip lateral rotation in side-lying, front squats, power cleans, box jumps, and resisted running in all planes • TBS: hang snatch, pull ups, bent over barbell rows, neutral spine core strengthening in supine/prone/quadruped, plank holds in all planes, treadmill running • Core strengthening/stabilization exercises • Balance and proprioception exercises	• PCL Jack brace • PT modalities as needed for pain control • TLS: broad Jumps, tuck jumps, drop jumps • TBS: Shuttle run, three-cone drill, high knee skipping and sprinting, reactionary drills, bear crawls, blocking drills • Core strengthening/stabilization exercises • Balance and proprioception exercises progressed • Noncontact return to play after 10 weeks • Full-contact return to play when return to sports criteria met

- Repetition tempo: exercises are performed in an explosive manner, controlling the eccentric portion and exploding throughout the concentric phase as fast as possible
- Training frequency: 3 days per week with cardiovascular, core, stretching, and joint mobilization exercises occurring during warm up, cool down, and off days
- Specific exercises used in the training (Figure 33-48):
  - Straight leg raises (Figure 33-48*A*)
  - OKC knee extension (Figure 33-48*B*)
  - Squats two legs (Figure 33-48*C*) and 1 leg (Figure 33-48*D*)
  - Lunges (Figure 33-48*E*)
  - Bench press (Figure 33-48*F*)
  - Pullups (Figure 33-48*G*)
  - Leg press (Figure 33-48*H*)
  - Rows (Figure 33-48*I*)
  - Calf raises (Figure 33-48*J*)
  - Resisted walking/running (Figure 33-48*K*)

Application of Chronic Training Variables

- Patient form with all exercises is monitored for compensation strategies caused by prior training errors or recent injury
  - Exercise intensity and volume is adjusted to allow for perfect form throughout training

Phase II: Performance Enhancement Training Techniques

Periodization

- An undulating periodization design is used for Phase II.
  - This model will incorporate more explosive and multijoint movements to maximize and progress the endurance, hypertrophy, and strength developed in Phase I, as well as further challenge the body through variability of exercise and functional motions.
- A 6- to 8-week mesocycle is used during Phase II with exercises progressed on weekly microcycles and advanced in difficulty every 6 to 8 weeks until the goals required to advance to Phase III are achieved.

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training with optimum posture
- Sensorimotor and balance training
- Core training
- Cardiorespiratory training
- Multi-planar training activities
- Training for optimum muscle balance
- Training for optimum muscle functional strength
- Training for optimum muscle functional power
- Neuromuscular dynamic stability exercises
- Training for speed, agility, quickness (SAQ)
- Plyometric training
- Functional training

Olympic Lifts Used in the Training Program

- Power clean (Figure 33-49*A*)
- Hang snatch (Figure 33-49*B*)

Training Principles Used in the Design of the Program

- The principle of overload continues to be applied in Phase II because the goal is to adequately overload the involved muscles followed by sufficient rest to further maximize power output through explosive functional and sport-related exercises.
- The principle of variation is used to vary demands on the body by undulating between a set of exercises performed on alternate days stimulating increases in strength and explosive power while allowing adequate rest.
- The principle of individualization is used to tailor the exercises to the specific deficits developed from the initial injury.
  - Following PCL injury, rehabilitation patients will demonstrate quadriceps weakness and atrophy as well as hamstring weakness secondary to forced disuse during the protection phase of rehabilitation.
    - These deficits may continue into return to sport training.
    - Patients may also demonstrate chronic deficits such as hip and core weakness, which must be addressed to further reduce risk of future knee injuries.

Application of Acute Training Variables

- Repetitions: three to six
- Sets: three to five
- Rest interval: 1 to 3 minutes between exercises and sets
- Intensity: High
- Repetition tempo: 311 (3-second eccentric phase, 1-second pause at end of motion, and 1-second explosive motion through the concentric phase)
- Training frequency: 3 days per week with cardiovascular, stretching, joint mobility, and core exercises performed on off-days as well as incorporated into warm up and cool down phase of training days. Exercises are divided into groups such as Group A and Group B. Exercise groups are performed on alternate training days. For example, Exercise group A will be performed on Monday and Friday. Exercise group B is performed on Wednesday. The order is switched the next week to avoid doing the same exercise group to training days in a row.
- Specific exercises used in the training (Figure 33-50)
  - Front squats (Figure 33-50*A*)
  - Power clean
  - Box jumps (Figure 33-50*B*)
  - 12- to 14-inch box stepups (Figure 33-50*C*)
  - Bent over barbell rows (Figure 33-50*D*)
  - Pull ups
  - Hang snatch
  - Resisted band walking

FIGURE 33-48. Specific exercises used during training: straight leg raises (**A**), OKC knee extension (**B**), two-leg squats (**C**), one-leg squats (**D**), lunges (**E**), bench press (**F**), pull ups (**G**), leg press (**H**),

FIGURE 33-48, cont'd rows (**I**), calf raises (**J**), and resisted running (**K**).

FIGURE 33-49. Olympic lifts used: power clean (**A**) and hang snatch (**B**).

- Band resisted hip external rotation in side-lying position (Figure 33-50*E*)
- Resisted running in all planes

Application of Chronic Training Variables

- Posture and form during exercise is monitored throughout the phase.
  - Jump and landing mechanics are evaluated to identify habitual patterns that may lead to excessive stress to the knee and healing ligament.

Phase III: Sport-Specific Training

Periodization

- Macrocycles: Macrocycle periodization is used in the last phase.
  - The goal is to peak the athlete's performance and perform return to sports testing corresponding with return to the next game when the injury occurs in season.
- Microcycles: Microcycle periodization uses a weekly cycle with the athlete progressing each week with peak performance testing each week to establish an estimated return to play.
  - Football games are played on a weekly basis; therefore the goal is to reach peak performance and return

FIGURE 33-50. Specific exercises used during training: front squats (**A**), box jumps (**B**), 12- to 14-inch box step ups finish by driving the knee up (**C**), bent over rows (**D**), and band resisted hip external rotation in side-lying position (**E**).

to play status at the end of the week (Friday), allowing for adequate rest before play on Saturday or Sunday.

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Sensorimotor and balance training
- Core training
- Cardiorespiratory training
- Multi-planar training activities
- Training for optimum muscle balance
- Training for optimum muscle functional strength
- Training for optimum muscle functional power
- Neuromuscular dynamic stability exercises
- Training for speed, agility, quickness (SAQ)
- Plyometric training
- Functional training
- Sport-specific training

Olympic Lifts Used in the Training Program

- Power clean (see Figure 33-49*A*)
- Hang snatch (see Figure 33-49*B*)

Training Principles Used in the Design of the Program

- The principle of individualization is used in Phase III as exercises are tailored to the demands of football play and more specifically the demands of the athletes position
- The principles of specificity: Specific adaptation to imposed demands (SAID) is applied through simulation of specific high-risk scenarios seen during game play
  - Blocking drills for lineman and simulated contact with tackling dummies for ball carriers as well as high-speed cutting and sprinting

Application of Acute Training Variables

- Repetitions: six to eight
- Sets: one to two
- Rest interval: 30 seconds between sets, 60 seconds between exercises
- Intensity: High
- Repetition tempo: Fast with explosive movements, 1- to 3-second pause on stop landings
- Training frequency: 3 days per week
- Training duration: 2 to 4 weeks
- Specific exercises used in the training:
  - Drop jumps (Figure 33-51*A*)
  - Tuck jumps (Figure 33-51*A,B*)
  - Broad jumps one leg (Figure 33-51*C*) and two leg (Figure 33-51*D*)
  - Three-cone drill (Figure 33-51*E*)
  - High knee sprinting/skipping (Figure 33-51*F*)

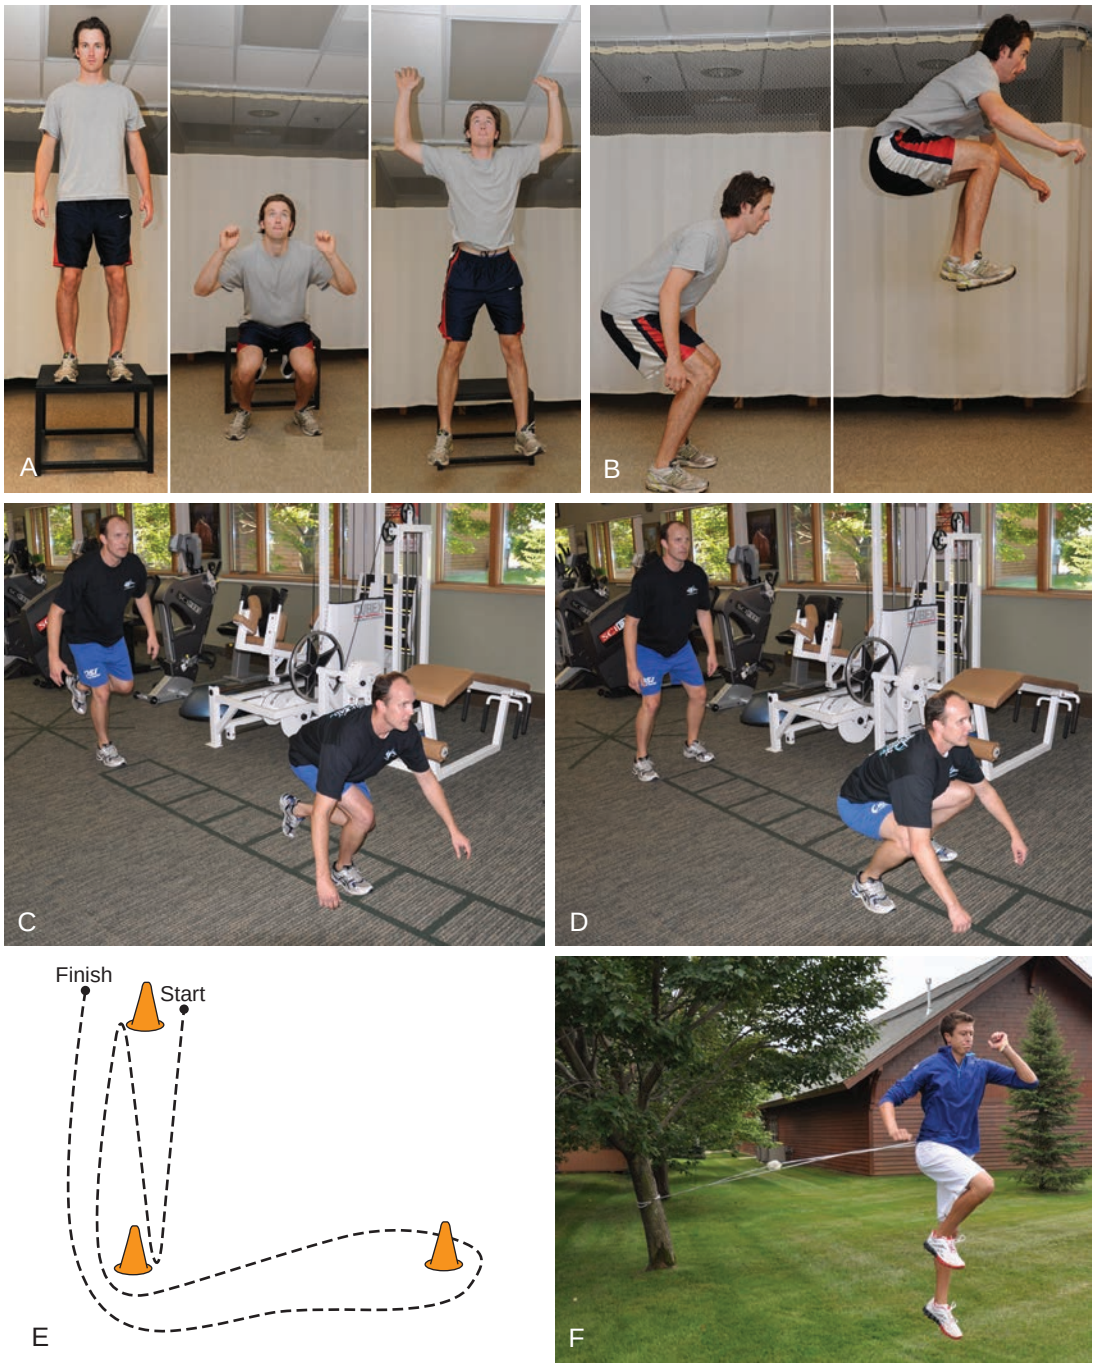

FIGURE 33-51. Specific exercise used in training: drop jumps (**A**), tuck jumps (**B**), broad jumps one leg (**C**), broad jumps two legs (**D**), three-cone drill (**E**), high knee skipping (**F**),

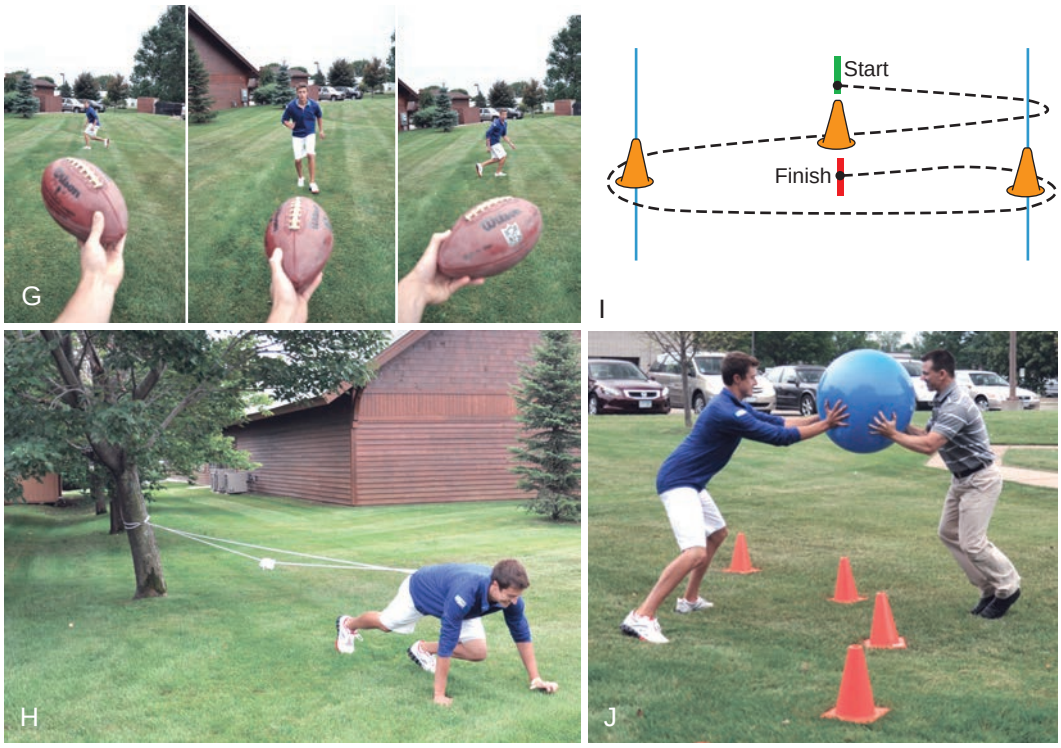

FIGURE 33-51, cont'd reactionary sprinting drills to visual/audible command (**G**), bear crawls for linemen (**H**), shuttle run (**I**), and lateral shuffle blocking drills for offensive linemen (**J**).

- Reactionary sprinting drills to visual and audible commands (line backers, defensive backs, wide receivers) (Figure 33-51*G*)
- Bear crawls (defensive linemen, offensive linemen) (Figure 33-51*H*)
- Shuttle run (Figure 33-51*J*)
- Lateral shuffle blocking drills (offensive linemen)

Application of Chronic Training Variables

- Focus in Phase III is placed on optimal takeoff and landing mechanics, proper lower extremity alignment during all jumping, cutting, and sport simulated drills
  - Proper lower extremity alignment is emphasized to reduce risk of injury, decrease loads on the involved knee, and maximize force production

Sports Performance Testing

General Information

- General history: A general background on the athletes playing position, skill level (first, second, or third string), and primary complaints is obtained.
  - Athletes with low-grade PCL injuries may complain less about instability or giving way and more likely describe a feeling of something being wrong.
  - Additionally, patients may complain of swelling in the knee following a traumatic episode involving falling onto a flexed knee or a direct blow to the tibia.
- Subjective questionnaires: IKDC Subjective Knee Evaluation Form
- Medical history: Athletes should be questioned regarding past medical history to ascertain any alternate diagnosis or conditions that may contribute the current complaints or complicate the healing time frame.
- Sports injury history: Sports injury history must be reviewed to establish the chronicity of the current condition
  - Athletes may present with more instability than expected from the mechanism of injury indicated that the current injury may be an acute injury imposed on chronic condition
  - Potential chronic conditions will have less chance of healing than an acute condition
    - A history of previous ligamentous or meniscal injuries may compound the observed instability and slow healing (e.g., an associated posterior lateral corner injury may result in failed conservative treatment for an acute PCL injury).
- Surgical history: A comprehensive surgical history must be obtained.
  - Athletes with previous ligamentous reconstructions or meniscal debridement may demonstrate residual laxity.
- Chronic conditions/medication: Chronic medical conditions as well as a current medication list (both prescription and over the counter) must be obtained and reviewed for potential conditions or medications that may slow healing.

Objective Tests

- Physiological assessments: Knee range of motion, manual muscle testing to associated hip musculature, assessment of gait pattern
  - Performed before and after Phase I
- Body composition tests: Circumference measurements to document quadriceps atrophy
  - Comparison made to uninvolved limb
  - Performed before phase I and after Phase II
- Static/dynamic postural assessments: posterior drawer testing
  - Performed before phase I and after each Phase II
  - Objectively better with PCL stress radiographs
- Dynamic muscle performance testing: Isokinetic testing for quadriceps and hamstrings strength
  - Hamstring to quadriceps ratio of the involved limb and comparison of quadriceps strength in the uninvolved limb
  - Performed before transition from phase II to Phase III
- Movement performance testing: One leg triple hop, crossover hop, and 6-meter hop testing
  - Comparison made to the uninvolved limb
  - Performed at end of Phase III
- Sport-specific testing: Simulated blocking drills, three-cone drill, cutting with visual and verbal curing for change in direction, shuttle run
  - Performed at end of Phase III

Specific Criteria for Progression to the Next Stage to Determine Readiness for Football

- Athletes must demonstrate 5/5 knee extension strength on manual muscle test, full active knee range of motion, and normalized gait to progress from stage I to stage II
- Athletes must demonstrate normal single leg squat to 60°, normal single leg hop, less than 15% deficit in quadriceps strength with isokinetic testing at 300° and 180° per second to progress from stage II to stage III
  - Negative posterior drawer sign as well

Specific Criteria for Release to Unsupervised Complete Participation in Football

- Athletes must demonstrate normal drop jump mechanics from a 12-inch box, no greater than 10% deficit in the involved lower extremity with one leg triple hop, one leg crossover hop, and one leg 6-meter hop test.
- There must be no complaints or evidence of instability or giving way with daily or sport simulated activities, and no evidence of knee joint effusion.

Recommended Ongoing Exercises

- Athletes must maintain an adequate quadriceps strengthening program throughout their career and should remain vigilant in routine jumping/landing drills

Evidence

Dick R, Ferrara MS, Agel J, et al: Descriptive Epidemiology of Collegiate Men's Football Injuries: National Collegiate Athletic Association Injury Surveillance System, 1988–1989 Through 2003–2004. *J Athl Train* 42(2):221–233, 2007.

A review of 16 years of injury data for men's collegiate football to identify ways to prevent injuries in athletes. The results show game injury rates were more than nine times higher than practice injury rate. The knees specific injury rate was 13.4 times higher in games as compared with practice. (Level IV evidence)

Fowler PJ, Messieh SS: Isolated posterior cruciate ligament injuries in athletes. *Am J Sports Med* 15(6):553–557, 1987.

Prospective study of isolated posterior cruciate injuries seen in 13 athletes diagnosed clinically and confirmed by arthroscopy. Patients were treated nonoperatively on a physiotherapy routine and followed for an average of 2.6 years. All patients were able to return to their previous activity and experienced no limitations with their injured knees. Concluded acceptable functional stability does not require an intact PCL and nonoperative treatment could be an acceptable short alternative to surgical reconstruction. (Level III evidence)

Jacobi M, Reischl N, Wahl P, et al: Acute isolated injury of the posterior cruciate ligament treated by a dynamic anterior drawer brace. *J Bone Joint Surg Br* 92-B:1381–1384, 2010.

Treated 21 patients with an isolated tear of the PCL for 4 months nonoperatively using a functional brace. Initial and follow-up stability was tested by Rolimeter arthrometry and radiography and clinical outcomes were measured using the Lysholm score, Tegner score, and International Knee Documentation Committee scoring system at 1 and 2 years. Found that the applied treatment produced a good or excellent functional result in all patients. Concluded the PCL has an intrinsic healing ability and will heal with less attenuation if the tibia is reduced to the proper anatomical position. (Level IV evidence)

Parolie JM, Bergfeld JA: Long-term results of nonoperative treatment of isolated posterior cruciate ligament injuries in the athlete. *Am J Sports Med* 14(1):35–38, 1986.

Long-term study of 25 athletes who received nonoperative treatment of isolated PCL injuries with follow-up averaging 6 years. Patients were evaluated with a questionnaire and objectively with clinical examination, x-ray films, Cybex II dynamometer, and KT-1000 knee arthrometer. Found that 80% of the patients were satisfied with their knee with 84% returning to their previous sport. Concluded that if athletes with isolated PCL injuries maintain muscle strength, the majority should return to sports without lingering disability. (Level IV evidence)

Patel DV, Allen AA, Warren RF, et al: The nonoperative treatment of acute, isolated (partial or complete) posterior cruciate ligament-deficient knees: An intermediate follow-up study. *HSSJ* 3:137–146, 2007.

Retrospective cohort study that identified 57 patients with an acute, isolated PCL tear that were treated nonoperatively. Clinical, radiographic, and functional assessments were performed with an average follow-up of 6.9 years. The authors concluded that most patients with acute, isolated PCL injuries do well with nonoperative treatment during intermediate follow-up. (Level III evidence)

Shelbourne KD, Davis TJ, Patel DV: The natural history of acute, isolated, non-operatively treated posterior cruciate ligament injuries. A prospective study. *Am J Sports Med* 27(3):276–283, 1999.

Prospective study of 133 patients with acute, isolated, non-operatively treated PCL-deficient knees. Mean follow-up after initial diagnosis of PCL injury was 5.4 years. the authors concluded that most cases of patients with acute, isolated PCL injuries can obtain satisfactory knee function when managed by nonoperative care. (Level III evidence).

Multiple Choice Questions

QUESTION 1. When rehabbing a football player with a posterior cruciate ligament injury, what should the training focus on during Phase I to reduce the risk of injuries and prevent stress on the healing ligament?

A. Proper form/posture during exercises
B. Maximum resistance
C. Endurance enhancement
D. Flexibility

QUESTION 2. Which of the following principles are used during Phase II of rehabilitation for a football player with a PCL injury?

A. Overload
B. Variation
C. Individualization
D. All of the above

QUESTION 3. Which of the following criteria must be met to progress an athlete from stage I to stage II during rehabilitation?

A. Full passive ROM
B. 5/5 knee extension strength
C. Quadriceps strength greater than 80% of the unaffected side
D. All of the above

QUESTION 4. Which of the following criteria must be met to progress an athlete from stage II to stage II during rehabilitation?

A. Normal single leg squat to 60°
B. Normal single leg hop
C. A and B
D. None of the above

QUESTION 5. What criteria should be met to release an athlete to full participation in football activities without further supervision?

A. No evidence of instability or giving way with sports-simulated activities
B. No evidence of instability or giving way with normal daily activities
C. No greater than 10% deficit in the involved lower extremity with one-leg triple hop
D. All of the above

Answer Key

QUESTION 1. Correct answer: **A** Proper form during therapy is critical to reduce injury risk and prevent substitution during exercises that can recruit the hamstrings and place undue stress on the healing PCL. Proper form and posture should be emphasized throughout each exercise and monitored carefully during training. Maximum resistance should not be undertaken until the athlete is well on the way to recovery and bears no value to preventing injury. Endurance training is important to prevent muscle atrophy and may play a role in injury prevention, but is not as important as proper form/posture. Flexibility training can prevent muscle shortening and help restore normal joint mechanics and is always important to prevent injury, but during therapy proper form and posture are more important. (see Phase I)

QUESTION 2. Correct answer: **D** Each of the principles listed in the preceding is used during Phase II of rehabilitation. Phase I focuses on progression and overload, whereas Phase III uses individualization and specificity. (see Phase II)

QUESTION 3. Correct answer: **B** To advance from stage I to stage II the patient should demonstrate full active range of motion, a normalized gait, and 5/5 knee extension strength. Quadriceps strength and passive range of motion are not criteria to progress from stage I to II. (see Sports Performance Testing)

QUESTION 4. Correct answer: **C** Athletes must demonstrate normal single leg squat to 60°, normal single leg hop, and less than 15% deficit in quadriceps strength with isokinetic testing at 300° and 180° per second to progress from stage II to III. In addition, athletes should have a negative posterior drawer test. (see Sports Performance Testing)

QUESTION 5. Correct answer: **D** Athletes must demonstrate normal drop jump mechanics from a 12-inch box, no greater than 10% deficit in the involved lower extremity with one leg triple hop, one leg crossover hop, and one leg 6-meter hop test. There must be no complaints or evidence of instability or giving way with daily or sports-simulated activities, and no evidence of knee joint effusion to be released from the care of a physical therapist. (see Sports Performance Testing)

BEYOND BASIC REHABILITATION: RETURN TO JOGGING AFTER MULTILIGAMENT KNEE RECONSTRUCTION

Nathan L. Cafferky, MD, Gregory C. Fanelli, MD, and Craig J. Edson, MS, PT, ATC

Introduction

ASPECTS OF JOGGING THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- Muscle strength
  - Adequate ability to contract with sufficient force to range the knee joint
- Coordination
  - The ability to allow for smooth contraction and relaxation of the antagonistic muscle groups of the leg to allow for fluid motion
- Range of motion
  - Ability to allow for sufficient physiologic motion through the knee joint
- Ligamentous stability
  - The ability of the knee joint to resist internal and external forces of derangement
- Proprioception
  - The ability for the patient to appreciate the location of knee joint in space

Multiligament Knee Injuries: Key Aspects

- Jogging
  - The ability to jog is a major stepping stone in returning to athletics after a ligamentous knee injury and subsequent surgery.
  - Popularized by Arthur Lydiard in the 1960s and 1970s[1]
  - Definition
    - Running at a slow and leisurely pace
- Multiligamentous knee injuries are the result of knee dislocations or subluxations
  - Two distinct categories
    - High-energy injuries
      - Related to motor vehicle accidents
      - Falls from height
    - Low-energy injuries
      - Typically associated with athletic injuries.
        - Football
        - Soccer
        - Snow skiing
  - Associated injuries
    - A careful initial evaluation of the extremity of the injured patient is of critical importance since the incidence of neurovascular damage is directly proportional to the energy of injury.
  - Further differentiation of multiligamentous knee injuries can be categorized into different directions in which the tibia is dislocated or subluxed in relation to the femur. Although reports vary, anterior and posterior dislocations appear to be the most common.[2,3]
    - Anterior
      - Result from hyperextension injuries
    - Posterior
      - Result from when an anterior-to-posterior force is directed against the proximal tibia with the knee at 90° of flexion[4]
    - Lateral
      - Result from medial-to-lateral (varus) force
    - Medial
      - Result from a lateral-to-medial (valgus) force
    - Rotational
      - Result from pivot injuries
  - Incidence
    - Knee dislocations are rare
      - One review article stated their institution had 14 knee dislocations out of 2 million admissions over a 50-year period.[5]
    - However, it is felt that the true incidence of knee dislocations is under reported because it is believed that a large portion of knee dislocations spontaneously reduce.[6] It has been speculated that it may be as high as 50%.
  - Initial treatment
    - High index of suspicion is required based on the events surrounding the accident
    - Consists of reduction and stabilization of the knee joint
    - Considered an orthopaedic emergency
    - Extensive evaluation consisting of performing a thorough history and physical, radiographic analysis such as x-rays and MRI studies, and even vascular studies when indicated
  - Surgical reconstruction using allograft, autograft or a combination of both can be used[6]
    - Adequate time should be given to allow for the incorporation of ligamentous grafts. Thus, a slow and methodical approach to rehabilitation allows the patient the ability to return to the activity of jogging and in the end, their respective sport.

Return to Jogging After Multiligamentous Knee Reconstruction: Literature

- Rehabilitation after multiligamentous (ACL, PCL, MCL) knee reconstruction
  - The rehabilitation of a multiligamentous knee following surgical reconstruction can be separated out into four distinct phases.
  - Each phase has distinct goals and exercise programs associated with it (Table 33-1).

Table 33-1 Multiple Ligament Reconstruction Rehabilitation

	Goals	Program
Phase I: 0–6 weeks	Maximum protection of grafts Maintain patella mobility Minimize quadriceps atrophy Maintain full passive extension—locked long-leg hinged ROM brace Control pain and swelling	Nonweightbearing ambulation with crutches Brace locked in extension 24 h/day Cryotherapy Quad sets—enhance with low-intensity electrical stimulation or biofeedback Patella mobilization Low-intensity gastrocsoleus and hamstring stretching
Phase II: 6–10 weeks	Initiate weightbearing for articular cartilage nourishment Increase knee flexion gradually to 90°–100° Improve quadriceps tone and strength Improve proprioception Avoid isolated quadriceps and hamstring contractions	Begin partial weightbearing • Grossly 20% body weight and increase by 20% per week over the next 5 weeks to full weightbearing by the end of postoperative week number 10. Open brace to full flexion and discontinue brace for sleeping. Prone hangs Passive flexion exercises High-intensity electrical stimulation with knee at 60°–70° (optional) Initiate closed-chain strengthening once full weightbearing and quadriceps strength of 3+/5 or greater Advance proprioception Fit for functional brace after 10 weeks. Discontinue ROM brace.
Phase III: 10 weeks–6 months	Progress closed-chain strengthening Initiate open-chain quadriceps strengthening by end of month 4. Initiate straight-line jogging at end of month 5. Increase knee flexion to at least 120° by end of month 6. Improve cardiovascular endurance.	Progressive resistive closed-chain exercises avoiding flexion beyond 70° Isolated quadriceps strengthening at end of month 4 Single-leg proprioception on unsteady surface Aggressive flexion exercises if necessary Consider manipulation under anesthesia if ROM is <90° by end of month 4 Hip passive resistance exercises Straight-line jogging at end of month 5 Initiate low-intensity plyometrics at end of month 6
Phase IV: 6–12 months	Maximum flexion 10°–15° degree terminal flexion loss is common Quadriceps strength 90% or greater of nonsurgical leg Progress to sport-specific activities Return to sports between month 9 and 12	Progression of strengthening, conditioning, and agility exercises to achieve goals Progressive plyometric proprioceptive program ("jump program") Return to sports if the following criteria are met: • Minimal or no pain and swelling • Completion of all functional tests within 10% of the uninvolved side • Ability to spring without any gait alteration • Compliance with functional bracing

Reproduced with Permission from Edson CJ, Fanelli GC, Beck JD: Rehabilitation after multiple-ligament reconstruction of the knee. *Sports Med Arthrosc Rev* 19:162–166, 2011.

- A carefully orchestrated approach to rehabilitation among the orthopedic surgeon, the physical therapist, and most importantly the patient is paramount for the patient to reach his or her expected goals.
- It requires a precarious balance between restoring range of motion and function to the knee without compromising the static stability and integrity of the grafted tissues.[7]
- Although rehabilitation protocols may vary from surgeon to surgeon, it is evident that rehabilitation needs to be more conservative in this population than for those with an isolated ligament injury, such as an isolated ACL injury.[8]
- Rehabilitation can be slow and challenging for most patients, and realistically can take up to a year before unrestricted activity is permitted.
  - Deciding to allow a patient to return to jogging and sports is complex, and is discussed throughout the chapter.

Phase I (weeks 0 to 6): Immobilization and Nonweightbearing

- Phase I represents the patient's acute postoperative recovery phase.
  - Goals for Phase I:
    - Maximize protection of the grafts
    - Maintain patella mobility
    - Minimize quadriceps atrophy
    - Maintain full passive extension
    - Control pain and swelling
- Immediately following surgical reconstruction, the operative knee is placed into a long-leg hinged range of motion (ROM) brace locked in extension for 5 weeks.
  - The patient must wear this brace for 24 hours per day, with the exception of showering.

- The importance of locking the knee in full extension during this phase cannot be overestimated.
  - Full extension minimizes forces across the PCL.[9]
  - Prevents the development of early flexion contraction[7]
  - Healing of the PCL graft
  - Restoring static stability of the knee[10]
- Another strategic component to Phase I is that the patient is also instructed to maintain nonweightbearing (NWB) ambulation with crutches for the full 6 weeks.
  - However, the patient is permitted to stand statically in place and weight-bear across the knee while wearing the long-leg hinged ROM brace locked in extension.
  - This decreases the patient's chance of falls, as he or she has better static balance when standing on both legs.[7]
  - Also, occasional weightbearing is felt to stimulate ACL and PCL bone tunnel healing and graft incorporation, as well as promote the production of synovial fluid, which is also important for graft healing.
- The risk of Phase I is the development of quadriceps atrophy and inhibition as well as stiffness of the knee.
  - Although knee stiffness has been found to occur, early ROM of the knee has been found to be more detrimental to attaining static stability of the knee.
    - Thus leading to the maintenance of the long-leg hinged ROM brace locked in extension
    - The few patients who do develop knee stiffness can undergo a manipulation of the knee under anesthesia or arthroscopic lysis of adhesions once static stability of the knee is reached and maintained.[11]
  - Quadriceps atrophy and inhibition, on the other hand, is the most important factor to prevent, and may be the most challenging aspect of the patient's rehabilitation.
  - It has been shown that quadriceps weakness is more than just a result of disuse, but rather the result of reflex inhibition.
  - Reflex inhibition is a complex response to distorted afferent and efferent stimuli.
    - It is theorized that arthrogenic muscle inhibition is caused by reflex activity in which altered afferent signals originating from the injured and operative knee lead to diminished efferent motor drive of the quadriceps; thus causing muscular atrophy.[12]
- Exercises are recommended once the surgical bandages are removed to combat muscular atrophy.
  - The exercises include:
    - Self-patella mobilization and massage
      - Gentle self-manipulation of patella with quadriceps massage
    - Cryotherapy
    - Application of ice to operative knee to minimize inflammation
    - Electrical stimulation of quadriceps muscle
    - Transcutaneous electrical nerve stimulation and/or neuromuscular stimulation
    - Quadriceps sets and ankle pumps
    - Multiple repetitions of gentle isometric contractions of the quadriceps muscle with active dorsiflexion and plantar flexion of ankle joint
    - Low-intensity gastrocsoleus and hamstring stretching[7,12]
    - Gentle passive stretching of the gastrocsoleus and hamstring muscles
  - This program is initiated to help:
    - Minimize swelling
    - Prevent quadriceps atrophy
    - Improve blood flow to the quadriceps
- Only after having successfully achieved and maintained the goals for Phase I can the patient move on to Phase II of the rehabilitation program.

Phase II (weeks 6 to 10): Initiation of Weightbearing and Range of Motion

- Phase II represents the start of the patient's formal rehabilitation. At this point, the restrictions previously placed are liberalized. The patient is allowed to begin weightbearing ambulation, and the ROM brace is unlocked to allow for full flexion.
  - Goals for Phase II
    - Initiate weightbearing for articular cartilage nourishment.
    - Increase knee flexion gradually to 90° to 100°.
    - Improve quadriceps tone and strength.
    - Initiate proprioception training.
    - Avoid isolated quadriceps and hamstring contractions.
- Partial weightbearing with crutches is initiated.
  - Crutches and protective weightbearing minimizes the patient's risk of falling because of significant quadriceps atrophy. The patient is instructed to begin using 20% of his or her body weight to introduce weightbearing forces across the surgical graft and aid with articular cartilage nourishment.
    - The purpose of starting weightbearing at 20% of the body weight is to emphasize to the patient of the importance of maintaining partial weightbearing, and to give the individual a numerical limit that he or she should not exceed.
    - 20% of the patient's body weight can be calculated using a scale. The patient can then obtain a mental note for how much weight 20% feels like.
    - Example: 20% of 150 lb is 30 lb. The patient can apply 30 lb to the operative leg, thus giving the patient a sense of how much force he or she is allowed to apply to the surgical graft.
- It is important that passive flexion exercises in protection be started during this phase, completely avoiding isolated hamstring and quadriceps strengthening.
  - Attempted forced flexion by either the patient or therapist at this phase of rehabilitation may compromise the ligamentous grafts, which are still undergoing incorporation during this phase.

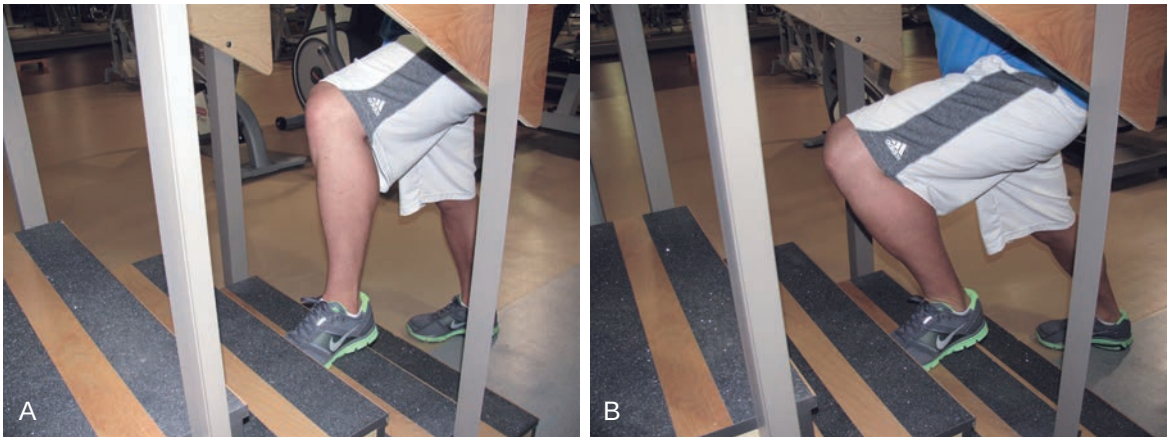

FIGURE 33-52. A,B, The stair stretch. The operative knee is placed on a step, and is then gently "rocked" forward until a comfortable stretch is felt by the patient.

- There have been reported incidences in which patients' grafts have torn just by being too aggressive during this phase of healing.[7]
- Passive knee flexion exercises exist that allow for improving ROM. Although many exercises exist, two such exercises include stair stretching (Figure 33-52) and passive-assisted heel slides (Figure 33-53).
  - Stair stretching is performed by having the patient place the involved knee on a stair and gently rocking forward. Passive knee flexion is achieved.
  - Passive-assisted heel slides can also be performed by using the nonsurgical leg to flex and extend the operative knee while the surgical knee maintains good alignment. Flexion is achieved until a stretch is felt, and then the knee is extended using the uninvolved leg.
- However, the initiation of flexion exercises can diminish a patient's ability to extend his or her operative knee. Thus, additional focus on extension during this phase is appropriate.
  - Prone hangs provide an excellent way for gravity to passively extend the knee.
    - The patient is placed in the prone position. With their body and thighs support, gravity is allowed to passively extend the knee. This further promotes passive range of motion to the surgical graft, thus minimizing the risk of graft compromise.
- Range of motion and weightbearing both progress gradually throughout this phase.
  - Range of motion
    - 90° of passive flexion is the goal that the patient should strive for at the end of week 10
  - Weightbearing
    - Increase weightbearing by 20% each week, until full weightbearing is achieved.[8]
  - Again, it is important to stress to the patient that this is a slow gradual process that should take 4 to 5 weeks.
- At the end of Phase II, once full weightbearing and quadriceps strength of 3+/5 is achieved, closed kinetic chain exercise programs, and proprioception training can be initiated.
  - Closed kinetic chain exercise programs (Figure 33-54).
    - Closed kinetic chain exercises progress the forces applied across the surgical graft in a controlled fashion. The operative extremity is kept in contact with an immobile surface throughout the entire exercise. Proper technique is emphasized, and

TIMELINE 33-4: **Return to Jogging After Multiligament Knee Reconstruction**

PHASE I (weeks 0 to 6)		PHASE II (weeks 6 to 10)
Weeks 0 to 2	**Weeks 2 to 6**	
• Long leg hinged ROM brace locked in extension • Surgical dressing maintained • NWB on operative extremity • Crutch ambulation	• Long leg hinged ROM brace locked in extension • NWB on operative extremity • Crutch ambulation • Surgical dressing removed • Patella massage/mobilization • Cryotherapy • Quadriceps sets • Ankle pumps • Low intensity gastrocsoleus and hamstring stretching	• Long leg hinged ROM brace unlocked • Allow for full flexion • WBAT on operative extremity • Starting at 20% body weight, advancing by 20% weekly • Continue crutch ambulation until WBAT is 100% • Crutch ambulation • Passive ROM exercises to 90°–100° • Stair stretching and passive-assisted heel slides • Initiate closed kinetic chain exercises • Electrical stimulation of quad muscle with knee at 60°–70° flexion

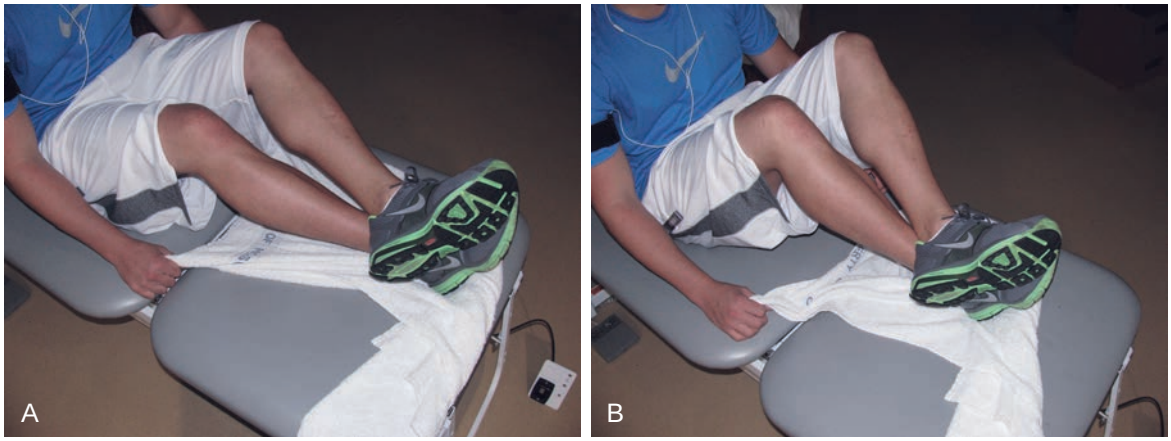

FIGURE 33-53. A,B, Passive heel slides. Many different techniques exist. The one depicted here occurs when the nonsurgical leg is used to flex and extend the operative knee while the surgical knee maintains good alignment.

FIGURE 33-54. Closed kinetic chain exercises. Squats are an excellent example of closed kinetic chain exercises. By placing a ball in between the patient's knees, adequate posture and biomechanics are enforced and maintained.

repetitions vary on the patient's ability and comfort level. Two such exercises are:
  - Lunges
    - With the operative knee placed in a forward position from the patient's body, the operative knee is flexed to 90° and then extended. The nonoperative knee is placed posteriorly, and allowed to flex to a point of comfort.
  - Squats
    - Legs are placed shoulder width apart. The patient is allowed to squat, similar to sitting down in a chair, and flex knees until 90° of flexion is achieved. Then the patient stands back up. This can also be performed by using a squat machine.
- Proprioception training (Figure 33-55)
  - Proprioception training provides neurological and biomechanical feedback to the patient to regain muscular coordination and control of the operative limb. It also re-establishes a sense of the operative limb in space.
    - Balance board
      - Double- and single-legged balance board training can be performed depending on the

TIMELINE 33-4: **Return to Jogging After Multiligament Knee Reconstruction** (Continued)

PHASE III (weeks 10 to 26)	PHASE IV (weeks 26 to 52)
• Change to multi-stability functional knee brace • Progressive resistive closed kinetic chain exercises • Avoid flexion knee beyond 70° • Single-leg proprioception exercises • Increase ROM/flexion exercises • Goal is 100°–110° by third month If ROM <90° by fourth month, will require manipulation under anesthesia • Goal is 120° by sixth month • Isolated quadriceps strengthening at end of fourth month • Hip passive resistance exercises • Stationary bicycle exercises • Straight-line jogging at end of fifth month • Initiate low-intensity plyometrics at end of sixth month	• Continue multi-stability functional knee brace • Progression of strengthening, conditioning, and agility exercises • Progressive plyometric proprioceptive program ("jump program") • Maximum flexion 10°–15° terminal flexion loss is common Quadriceps strength 90% or greater of nonsurgical leg • Return to sports between month 9 and 12 • Return to sports if the following criteria are met: • Minimal or no pain and swelling • Completion of all functional tests within 10% of the uninvolved side • Ability to spring without any gait alteration • Compliance with functional bracing

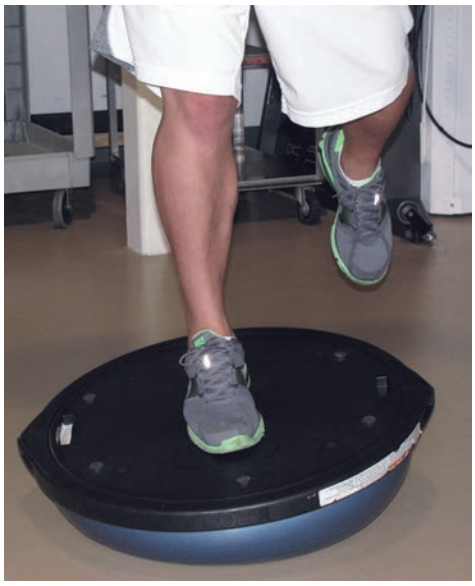

FIGURE 33-55. Balance board. Excellent way to enhance proprioception in the operative knee. The operative leg is used on the balance board. This is worked on until the patient is able to maintain his or her own balance without the use handrails.

patient's ability and comfort level. Using a platform with a round under-surface, the patient attempts to improve his or her ability to stabilize himself or herself and thus improve overall balance.

- If the patient has successfully achieved and maintained the goals for Phase II, he or she is allowed to progress to Phase III of the rehabilitation program.
  - When the patient is able to weight bear as tolerated on the operative leg, has regained 3+/5 strength in the quadriceps, and is able to perform closed kinetic chain and proprioception exercises without much discomfort, he or she is allowed to advance to Phase III.
  - At this point, the long-leg locking ROM brace can be discontinued, and the patient is fitted with a functional knee brace.
  - The functional knee brace should be multi-stability–specific so it prevents anteriorly and posteriorly directed forces on the tibia while also supporting the medial and lateral structures.
  - This brace should be worn throughout the remainder of the patient's rehabilitation.
  - This occurs typically by postoperative week 10.

Phase III (weeks 10 to 26): Increasing Range of Motion and Improving Muscle Conditioning

- Phase III represents the progression to more advanced strengthening and conditioning programs.
  - Goals for Phase III
    - Increase knee flexion.
    - Progress closed-chain strengthening.
    - Initiate open-chain quadriceps strengthening and straight-line jogging.
    - Improve cardiovascular endurance.
    - Continue proprioception conditioning.
- Studies have shown that both the ACL and PCL have mechanoreceptors that communicate directly with the central nervous system.[13,14]
  - The tearing of these ligaments and subsequent reconstruction leads to knee joint dysfunction, thus leading to joint laxity and muscular dysfunction.
  - Consequently it is imperative to train the surrounding knee musculature and mechanoreceptors so that joint proprioception is restored during gait and daily activities.
  - Exercises used during this period of rehabilitation focus on sensorimotor and balance training, and training toward optimum muscle functional strength.
    - This can be accomplished by having the patient continue to wear his or her multi-stability–specific knee brace and perform:
      - Continued proprioception training.
    - Balance board (see Figure 33-55) is an excellent way for the recovering athlete to focus on improving his or her overall balance through the knee joint, by re-training the knee mechanoreceptors.
      - Progressive closed-chain strengthening exercises.
        - Closed kinetic chain exercises not only improve muscle function and strength, but are also an excellent way to aid in the recovery of proprioception.
- Closed kinetic chain exercises have been shown to have decreased shear forces across the tibiofemoral joint, as compared with open kinetic chain exercises because of the axial orientation of the applied force and muscular co-contraction.[15]
  - This idea has been brought into question by the Beynnon et al.,[16] who found that closed kinetic chain exercises produce similar strain patterns as unweighted open chain exercises. However, Beynnon also found that performing weight resisted open chain exercises significantly increases the strain across the surgical graft, whereas adding resistance to closed chain exercises does not significantly increase the strain pattern across the surgical graft.
    - Open chain exercises are performed in which the foot of the operative leg is free in space, such as hamstring curls or leg extensions.
      - It is important to begin closed chain exercises with only using the patient's body weight, because the patient's quadriceps muscles may not be at full strength yet.
        - As previously stated, lunges and squats are excellent examples of these types of exercises.
  - It is imperative that the patient focus on good structural posture, and limit active knee flexion to 60° during this period of rehabilitation.
    - The initial 60° arc of knee flexion has been found to have similar quadriceps and hamstring strength ratios.[17]
      - This minimizes tibial translation
      - Decreases the potential risk of injuring the ligamentous grafts

- This is also another important reason why early prevention of quadriceps atrophy is important, so that quadriceps and hamstring strength ratios remain equal, thus limiting tibial translation.
- Once muscular strength and control improve, resistance exercises are implemented.
  - Muscular strength should be symmetrical with the contralateral, nonsurgical leg. Once the patient is able to balance himself or herself on the balance board, the patient has achieved adequate control of the operative leg.
  - A combination of both concentric and eccentric exercises can be used.
    - Concentric exercises occur when muscles shorten during contraction.
      - Resisted hamstring curls or resisted quadriceps extensions
    - Eccentric exercises occur when muscles Lengthen during contraction.
      - Known as "negative resistance" exercises
  - Studies have shown that the use of negative resistance training in combination with standard concentric exercises provides for a twofold greater increase in quadriceps peak cross-sectional area and volume.[18]
    - These exercises improve quadriceps recruitment and strength.
- The final step in re-establishing quadriceps muscular strength is the use of open kinetic chain exercises.
  - It is important that the patient and therapist be aware that open kinetic chain exercises can create larger anterior shear forces across the tibiofemoral joint than do closed chain exercises.[15,16] Thus these exercises are deferred until the 16 weeks of rehabilitation to allow the ligamentous grafts time to incorporate and strengthen.
    - Excellent examples of open kinetic chain exercises are:
      - Hamstring curls
      - Quadriceps extensions
    - These exercises are implemented gradually and with regard to the patient's subjective reports.[7]
  - Progressing to open kinetic chain exercises too quickly can lead to the development of anterior knee pain.
    - This is typically the result of an offset between the quadriceps and hamstring strength ratios, leading to excessive force across the knee structures. Thus the patellofemoral joint reaction forces are augmented.[7]
      - Patella tendonitis and patellofemoral chondromalacia are the most likely result that occur as the result of breakdown and inflammation of the cartilage and tendon.[7] This can be prevented with close monitoring of the patient's response to the exercises, and use of cryotherapy at the end of each exercise.[7]
- Although focusing on quadriceps strength is a large component of this phase of rehabilitation, it is also vital to not neglect the importance of improving ROM.
  - Setting ROM goals for the patient during this phase of therapy is important.
    - At the end of approximately the third month of rehabilitation, 100° to 110° of flexion should be achieved, progressing toward 120° of flexion by the sixth month of rehabilitation.
    - This is achieved by continuation of passive knee flexion exercises and the incorporation of active knee flexion exercises, as previously discussed.
- Once adequate quadriceps strength and knee ROM are achieved, progressive challenging exercises may be implemented. Quadriceps strength should be symmetrical to the contralateral nonoperative leg with near full pain-free symmetrical range of motion of the knee joints. This is typically achieved by the 20th week of rehabilitation.
  - At this point, straight-line jogging is allowed.
    - Initially the patient is monitored for altered gait biomechanics.[7]
      - If an obvious dysfunction is identified, the patient is prevented from jogging, and returns to working on ROM and strength training.
      - However, if no gait abnormalities are identified, the patient is allowed to continue with straight-line jogging.
        - This means that muscular strength and coordination of the operative leg are within normal limits for the patient.
- Near the end of Phase III of rehabilitation, the patient is instructed to continue addressing and promoting the following, which becomes an important part of his or her recovery.
  - Dynamic stabilization
    - Dynamic stabilization can be performed with the continuation of closed kinetic chain exercises such as wall sits and single leg squats.
    - A study in 2009 showed that PCL forces were significantly lower in one leg squats exercises up to 70° compared with the bilateral leg squats to 90°.[19]
      - Thus limiting closed chain exercises to 70° of flexion will help minimize excessive forces across the grafted PCL.
  - Proximal strengthening
  - Core body exercises
    - Properly performed situps and crunches are excellent ways to advance core strength.
      - Focused abdominal exercises. Full situps result in the entire back being lifted off the floor while crunches only lift the upper portion of the trunk of the floor. Both provide adequate core strengthening.
  - Cardiorespiratory training
    - Stationary bicycles are an excellent way to promote the patient's cardiopulmonary rehabilitation by maintaining the patient's targeted heart rate. This can be achieved by repetitions, sets, and tempo of training. Adjusting them as needed to meet the patient's demands and goals.
    - Stationary bicycles also provide a great way for the patient to work on the entire lower extremity.
      - Stationary bicycles promote:
        - Range of motion
        - Strengthening the gastrocsoleus muscle complex, quadriceps, hamstring, and hip flexors and extensors

- Stationary bicycling not only improves muscular strength and coordination, but also improves both muscular and cardiopulmonary endurance.
- Completing Phase III of rehabilitation is a significant accomplishment for the patient, and is typically finished by about the 24 weeks of rehabilitation.
  - Most patients are beginning to feel ready to return to activity.
    - However, it is important to remind and reinforce to the patient that he or she continue to require additional rehabilitation, and will likely not be ready to return to unrestricted activity for another 3 to 6 months.[7]
- Once the patient has achieved the goals of Phase III, which include improved knee flexion, progressive closed-chain strengthening, the initiation of open-chain quadriceps strengthening and straight-line jogging, improvement in cardiovascular endurance, then he or she is allowed to progress to Phase IV.

Phase IV (weeks 26 to 52): Improving Strength, Range of Motion, and Returning to Jogging (and Sports)

Attaining and maintaining maximum knee flexion and quadriceps strength is an important aspect of Phase IV. Phase IV is geared toward returning to sports and work-related activities.

- Goals for Phase IV:
  - Attain maximum flexion and quadriceps strength.
  - Progress to sport-specific activity.
  - Return to unrestricted jogging and sports.

Rehabilitation months 6 to 9 are typically a period of refining all previously mentioned exercises, as well as incorporating nonlinear jogging and cutting as well as low-level plyometrics.

- Plyometrics includes both double and single leg exercises.
  - This is the "jump program" (Table 33-2).
    - Focus is placed on the mechanics of landing and posture. The patient should be able to maintain the landing position for 2 to 5 seconds.
    - This is a progressive program that typically takes 6 weeks to complete.
    - It is designed to minimize potential risks of injury by increasing the load across the knee to enhance functional stability of the knee.[7,18,20-23]
    - The patient is allowed to advance to the next stage only after successfully completing the previous stage.
    - The patient is again monitored during this phase for the development of anterior knee pain, and measures are taken as previously stated, to prevent and treat this problem if it develops.
- The completion of the "jump program" should coincide with the ninth month of rehabilitation.
  - At this point, returning to unrestricted activity, such as jogging, is considered if the patient is able to meet certain criteria.
    - Has minimal or no pain and swelling
    - Has the ability to spring without any gait alteration. (Spring is assessed by comparing it to the contralateral leg.)
    - Compliance with functional bracing
    - Meets the functional testing goals of the operative knee, as described in the following

In the end, range of motion of the knee and leg neuromuscular function should be evaluated.

- It is expected that the patient will have a 10° to 15° loss of terminal flexion in the operative knee when compared with the uninvolved knee.
- It is important to quantify the operative knee and leg neuromuscular function before return to activity.

Table 33-2 The Geisinger HealthSouth/Geisinger Sports Medicine Jump Program

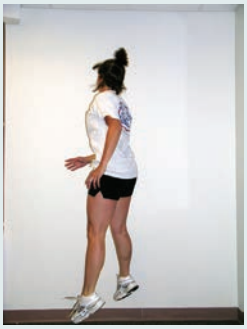
1.1.1.1.1 Platform Drop-Down Landing			Soft landing into knee flexion, avoiding the weaker leg falling behind the stronger leg.
			
Stand on an 8" platform.	Step off platform and prepare for landing into double leg stance.	Soft neutral landing in knee flexion: hold position for 2 seconds and repeat.	

Table 33-2 The Geisinger HealthSouth/Geisinger Sports Medicine Jump Program—cont'd

1.1.1.1.2 Tuck Jump			Simultaneous takeoff and landing with feet parallel to one another. Soft landing into knee flexion, avoiding the weaker leg falling behind the stronger leg. *Keep back and shoulders upright bringing knees up to chest and avoid slouching chest forward into the jump.*
			
Neutral semi-squat start position	Jump straight up and tuck knees up to chest.	Soft neutral landing in knee flexion: Hold position for 2 seconds and repeat.	
1.1.1.1.3 Squat Jump			Simultaneous takeoff and landing with feet parallel to one another. Soft landing into knee flexion, avoiding the weaker leg falling behind the stronger leg. *Avoid valgus of knees with initial squat position and in takeoff.* *Avoid a forward or lateral shift; should maintain symmetry in squat position.*
			
Neutral squat until fingertips touch the floor at outside of feet.	Jump straight up, raising arms overhead for maximal vertical leap keeping legs straight while airborne.	Soft neutral landing in knee flexion: Hold position for 2 seconds and repeat.	
1.1.1.1.4 Barrier Jumps—Side to Side			Simultaneous takeoff and landing in non-algus position with feet parallel to one another. Soft landing into knee flexion avoiding the weaker leg falling behind the stronger leg. *Jump up and slightly tuck knees to clear the barrier; adjust height of barrier accordingly if unable to clear it.*
			
Neutral semi-squat start position while standing beside a 6" barrier.	Jump up and across the cone. Keep knees bent while airborne.	Soft neutral landing in knee flexion: Hold position for 5 seconds and repeat.	

Continued

Table 33-2 The Geisinger HealthSouth/Geisinger Sports Medicine Jump Program—cont'd

180° Jumps			Simultaneous takeoff and landing in a nonvalgus position with feet parallel to one another. Soft landing into knee flexion, avoiding the weaker leg falling behind the stronger leg. *Do not attempt to turn before takeoff.*
			


Neutral semi-squat start position.	Jump straight up and rotate 180° to the right while in the air, keeping knees straight while in the air.	Soft neutral landing in knee flexion facing opposite direction from start: Hold position for 2 seconds and repeat in the opposite direction to the left.	
1.1.1.1.5 Broad Jump			Simultaneous takeoff and landing in a nonvalgus position with feet parallel to one another. Soft landing into knee flexion, avoiding the weaker leg falling behind the stronger leg. *Stable landing into deep knee flexion; if unable to maintain balance, instruct patient to shorten jump.*
			
Neutral semi-squat start position.	Jump up while advancing forward.	Soft neutral landing in knee flexion: Hold position for 5 seconds and repeat.	
1.1.1.1.6 Platform Jump-ups			Simultaneous takeoff and landing in a nonvalgus position with feet parallel to one another. Soft landing into knee flexion, avoiding the weaker leg falling behind the stronger leg. *Jump up and slightly tuck knees to clear the platform; reduce height of platform accordingly if unable to clear it.*
			
Neutral semi-squat start position standing behind an 8″ platform.	Jump up onto the platform.	Soft neutral landing in knee flexion: Hold position for 5 seconds and repeat.	

- Some objective means to measure knee and leg neuromuscular function is to perform the following:
  - Single-leg hop for distance
  - Single-leg vertical jumps for height
  - Shuttle runs
- The patient has successfully met the goals.
- When the patient is found to have neuromuscular function strength and range of motion within 10% of the uninvolved knee, he or she is allowed to return to unrestricted activity, such as jogging.[7]
  - However, if not, the patient must continue with rehabilitation until adequate strength and ROM are achieved.
  - This objective is typically satisfied sometime between the 9th and 12th month of rehabilitation.

Although knee bracing is controversial, it allows for an added level of stability. The eventual goal is to transition the patient out of the knee brace, and get him or her to rely on the knee's own static, dynamic, and muscular strength.

- Because of the complex nature of a multiligamentous knee injury and subsequent surgery, prophylactic knee bracing is continued throughout the formal rehabilitation period.
- Knee bracing becomes optional at the 18th rehabilitation month, and the patient should be encourage to continue bracing if he or she finds it beneficial.[7]

At the point in which the patient is released from rehabilitation and allowed to return to unrestricted activity, the patient has spent approximately 1 year recovering from multiligamentous knee reconstruction.

- It is important to remind the patient that maintaining muscle strength, ROM, flexibility, and proprioception in the operative knee is the best way to prevent reinjury in the future and provide the most satisfying long-term outcome.

Summary

- Multiligamentous knee injuries and subsequent surgery present orthopedic surgeons and physical therapists with a complex problem on how to provide appropriate rehabilitation for the patient.
- Although jogging is defined as running at a slow and leisurely pace, a significant amount of stress is placed across the knee joint.[24,25]
- Before allowing a patient to return to jogging and other activities, a methodical rehabilitation protocol must be followed.
- Appropriate rehabilitation results in a precarious balance between knee stiffness and knee function, while restoring ROM to the knee without compromising the static stability and integrity of the grafted tissues.[7]
- Although recovery can be anticipated to take approximately 1 year, studies support that good patient outcomes and satisfaction can be achieved following the methodical rehabilitation program outlined in this chapter.[7,26-34]

Evidence

Edson CJ, Fanelli GC, Beck JD: Rehabilitation after multiple-ligament reconstruction of the knee. *Sports Med Arthrosc Rev* 19:162–166, 2011.

A review article that outlines the overall rehabilitation protocol following a multiligamentous knee reconstruction. This article outlines the timeline and goals for the patient as they progress through rehabilitation. (Level V evidence)

Fanelli GC, Orcutt DR, Edson CJ: Current concepts: The multiple ligament injured knee. *Arthroscopy* 21:471–486, 2005.

This is a well-written review article over knee dislocations, ligamentous knee injury, and subsequent reconstruction techniques. (Level V evidence)

Li G, Pappannagari R, Meng Li MS, et al: Effect of posterior cruciate ligament deficiency in vivo translation and rotation of the knee during weightbearing flexion. *Am J Sports Med* 36:474–479, 2008.

Eight patients with a PCL injury to one knee and intact PCL in the contralateral knee were evaluated. Using MRI, three-dimensional models of the femur and tibia were created for both knees. Each knee was imaged during quasistatic weightbearing flexion (0° to 105°) using dual-orthogonal fluoroscopic system. Six degrees of freedom kinematics were assessed. Findings supported that PCL injuries not only affect anterior-posterior tibial translation, but also medial-lateral translation and rotation of the knee. PCL reconstruction should restore all planes of stability. (Level III evidence)

Lutz GE, Palmatier RA, An KN: Comparison of tibiofemoral joint forces during open-kinetic-chain and closed-kinetic-chain exercises. *J Bone Joint Surg Am* 75:732–739, 1993.

Five healthy subjects performed open-kinetic-chain extension, open-kinetic-chain flexion, and closed-kinetic-chain exercises at 30°, 60°, and 90°. Data from the electromyographic activity from the quadriceps and hamstrings, as well as load and torque across the knee joint were collected. A two dimensional biomechanical model was used. Open-kinetic-chain extension exercises produced maximum posterior shear forces at 30° flexion, and maximum anterior shear forces at 90° of flexion. Closed-kinetic-chain exercises produced significantly less posterior and anterior shear forces at all angles. (Level I evidence)

Roman PD, Hopson CN, Zenni EJ, Jr: Traumatic dislocation of the knee: A report of 30 cases and literature review. *Orthop Rev* 16:917–924, 1987.

Thirty cases of traumatic knee dislocations are reviewed. Nonoperative versus operative treatment and outcomes are assessed. Nonoperative treatment can result in a functional knee in low-demand patients, but for young active patients, early operative reconstruction, bracing, physical therapy to restore strength, and ROM provided the best outcomes. (Level III evidence)

Multiple Choice Questions

QUESTION 1. A football player sustains an injury to his right knee during a playoff game. A knee dislocation is identified. Which of the following physical exam findings is the most important to determine?

A. Range of motion of injured knee
B. Ligamentous stability of injured knee
C. Neurovascular status in injured leg
D. Muscular strength of injured leg

QUESTION 2. The operative knee is immobilized in extension during Phase I of rehabilitation. All except which of the following are important reasons to maintain full extension following multiligamentous knee reconstruction?

A. Forces across the PCL are minimized.
B. Causes knee stiffness, which improves postoperative recovery
C. Prevents the development of early flexion contractions
D. Allows for healing of the PCL graft and restoring static stability of the knee

QUESTION 3. Initiation of passive flexion exercises and protected weightbearing with crutches is an important part of recovery. However, being too aggressive with early ROM and ambulation can lead to which complication?

A. Tearing of the grafted tissues
B. Decreased articular cartilage nourishment
C. Falls
D. Patellar tendonitis

QUESTION 4. Closed kinetic chain exercises have been shown to be beneficial during recovery following multiligamentous knee reconstruction because of which of the following reasons?

A. Shear forces across the tibiofemoral joint are decreased by the axial orientation of the applied forces.
B. Tibial translation in relation to the femur is minimized.
C. Potential risk of injuring the surgical graft is decreased.
D. All of the above

QUESTION 5. At the completion of a methodical rehabilitation program following multiligamentous knee reconstruction, the patient can expect to have which functional deficit?

A. Continued quadriceps atrophy and weakness in the operative leg.
B. Permanent 10° to 15° loss of ROM in the operative knee.
C. Instability in the operative knee requiring lifelong bracing.
D. All of the above

Answer Key

QUESTION 1. Correct answer: **C** Documenting the neurovascular status of the injured leg is the most important in the acute setting, because the incidence of neurovascular damage is directly proportional to the energy of injury. (see Introduction)

QUESTION 2. Correct answer: **B** Early ROM of the knee has been found to be detrimental to attaining static stability of the knee. Immobilization in extension minimizes forces across the PCL, prevents flexure contraction, and allows for PCL graft healing with restoration of knee static stability. However, knee stiffness can be a problematic result. The few patients that do develop knee stiffness can undergo a manipulation of the knee under anesthesia or arthroscopic lysis of adhesions once static stability of the knee is reached and maintained. (see Phase I)

QUESTION 3. Correct answer: **A** Being too aggressive with ROM during this phase of recovery can lead to a catastrophic injury or tearing of the grafted tissues. This can ruin the patient's ability to ever return to preinjury status. Although falls are a concern during this phase of recovery, maintaining gentle passive ROM exercises and protected weightbearing not only minimize falls, but also improve articular cartilage nourishment and introduces weightbearing forces across the surgical graft that aid with graft healing and incorporation. (see Phase II)

QUESTION 4. Correct answer: **D** Closed kinetic chain exercises have been shown to decrease the shear forces across the tibiofemoral joint because of the axial orientation of the applied force and muscular co-contraction. This minimized tibial translation and decreases the potential risk of injuring the ligamentous grafts. (see Phase III)

QUESTION 5. Correct answer: **B** It is expected that the patient will have a permanent 10° to 15° loss of terminal flexion in the operative knee when compared with the uninvolved knee. Although leg weakness can be problematic, it is rarely permanent. Leg strength should be quantified and be within 10% of the uninvolved leg before returning to activity. Knee bracing also becomes optional after the 18th rehabilitation month (see Table 33-2).

Chapter 34

Medial Collateral Ligament Injuries

INTRODUCTION

Michael J. Battaglia II, MD

Epidemiology

Age

- 20 to 29

Gender

- 68% men, 32% women

Sport

- In general, virtually any sport, especially those involving contact or pivoting. Football, rugby, soccer, basketball and skiing are specific examples.

Position

- An isolated medial collateral ligament (MCL) injury may occur in virtually any player. There is a greater likelihood for players involved in contact.

Anatomy

- The MCL of the knee originates on the medial femoral condyle and approximately 5 cm distal to the joint line on the tibia. It has an average length of 11 cm and a width of 1.5 cm.
- The medial side of the knee is composed of three layers. The MCL resides in layer 2.[1] It is composed of a superficial and deep band and is the primary stabilizer to the medial knee[2,3] (Figure 34-1). The superficial MCL converges with the posterior oblique ligament, forming the posteromedial joint capsule. This structure has recently been shown to play an important role in stability as well.[4] The deep MCL forms a thickening in the middle portion of the medial joint capsule and has attachments to the medial meniscus. The MCL also has attachments to the semimembranosus muscle via several fibrous bands (Figure 34-2).

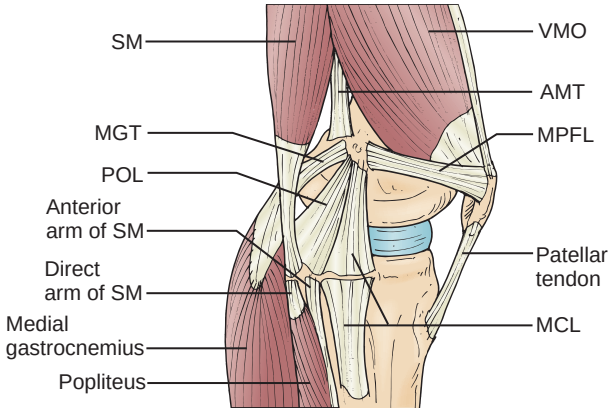

FIGURE 34-1. The superficial medial collateral ligament (medial aspect, left knee).

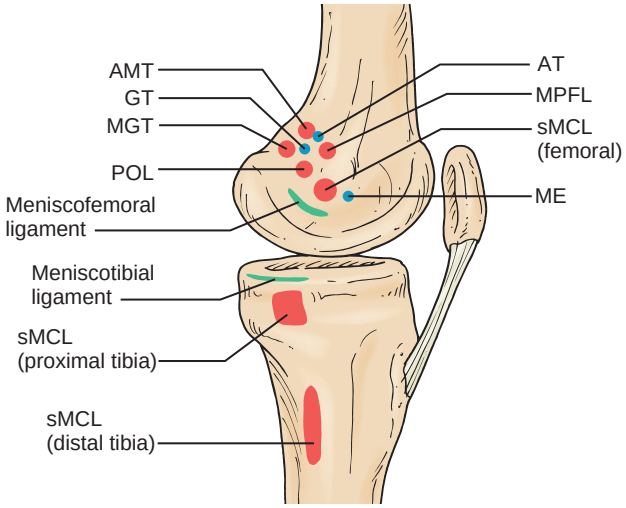

FIGURE 34-2. The medial knee bony attachment sites (medial aspect, left knee). (*AMT, adductor magnus tendon; AT, adductor tubercle; GT, gastrocnemius tubercle; ME, medial epicondyle; MGT, medial gastrocnemius tendon; MPFL, medial patellofemoral ligament; POL, posterior oblique ligament; SM, semimembranosus; VMO, vastus medialis obliquus.*)

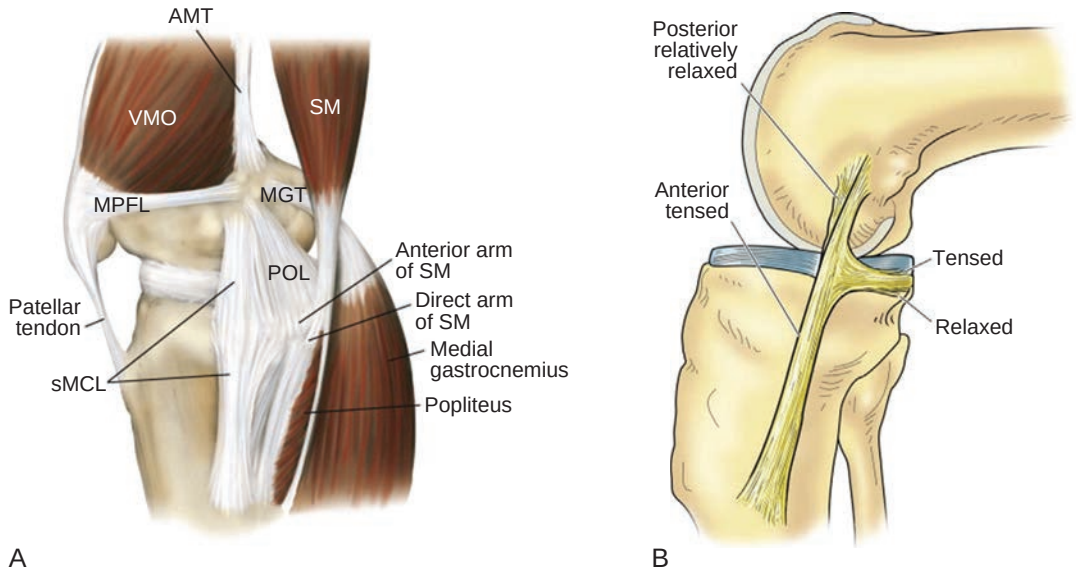

FIGURE 34-3. A, The medial right knee in extension. The entire medial collateral ligament (MCL) complex is on tension; however, the anterior aspect of the superficial MCL is slightly slackened versus the posterior components. AMT, Adductor magnus tendon; MGT, medial gastrocnemius tendon; MPFL, medial patellofemoral ligament; POL, posterior oblique ligament; SM, semimembranosus muscle; sMCL, superficial medial collateral ligament; VMO, vastus medialis obliquus muscle. **B,** The medial knee in flexion. Illustrates the posterior oblique ligament on slack and the anterior superficial MCL on greater tension than the posterior aspect. The darkened region denotes the deep MCL. The posterior oblique fibers become tenser in flexion.

- The MCL functions as a static stabilizer of the medial knee, resisting valgus and external rotation stresses. The superficial MCL is the primary restraint to valgus stress when the knee is positioned in slight flexion (Figure 34-3*A*,*B*).
- Most injuries to the MCL occur with a direct blow to the lateral knee while in slight flexion.
- The severity of MCL injuries is graded on a scale from I to III.
  - In a grade I injury, there is partial tearing of the ligament without laxity.
  - Grade II injuries consist of partial tissue tearing with laxity of up to 5 mm of joint opening.
  - Complete MCL ligament tears are grade III injuries and lead to joint instability with greater than 10° of joint opening.[5]

Pathophysiology

Intrinsic Factors

- Valgus deformity (increased Q angle) (Figure 34-4)
- Hip anteversion
- Previous injury (anterior cruciate ligament [ACL]) deficiency

Extrinsic Factors

- No difference between natural and synthetic surfaces in football
- Ski type/binding type (occurs more frequently with skiing than in snowboarding)

Traumatic Factors

- As the primary restraint to valgus instability, the MCL is most commonly injured by a direct blow to the lateral aspect of the knee with the foot planted (Figure 34-5).
- The MCL also provides significant restraint to external rotation of the tibia. Other mechanisms of injury include forced external rotation of the tibia with the foot planted (Figure 34-6) or forced external rotation with excessive valgus force in the unloaded extremity.

Classic Pathological Findings

- Local pain and edema
- Tenderness to palpation: careful palpation to determine exact site of injury (distal versus proximal MCL)

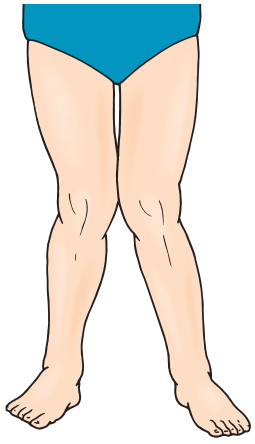

FIGURE 34-4. Valgus deformity.

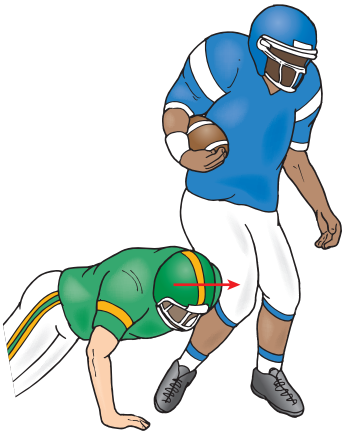

FIGURE 34-5. Lateral blow to the knee with foot planted.

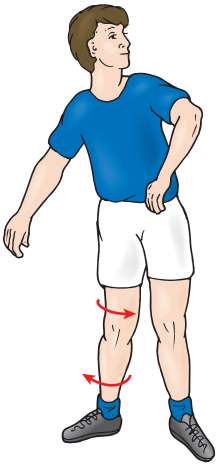

FIGURE 34-6. Forced valgus with external rotation of tibia with foot planted.

- Limited range of motion (ROM)
- Valgus laxity (Figure 34-7)

Clinical Presentation

History

- Blunt force to outside of knee
- Foot stuck, knee/body kept going (lateral or rotatory direction)
- Medial knee pain

Physical Examination

Abnormal Findings

- Positive valgus stress test for pain and/or laxity
- Tenderness to palpation: proximal or distal to medial joint line
- Local edema
- Limited ROM

Pertinent Normal Findings

- No anterior laxity
- ROM is limited by pain, no hard end-feel
- Negative meniscus signs

Imaging

- Radiographs to rule out avulsion fracture
- Magnetic resonance imaging (MRI) scans if suspected injury to other structures. Coronal T1-weighted images may show edema of the lateral femoral condyle. Posterior coronal cuts can be useful to confirm disruption of the MCL fibers.

Differential Diagnosis

- Meniscus: no pain/laxity with valgus stress test; on careful palpation, MCL proximal or distal to joint line, meniscus will be tender over the joint line (Figure 34-8*A, B,* and *C*).
- Combined ACL/MCL injury: knee effusion and anterior laxity with ACL rupture. Valgus laxity in extension may be indicative of concomitant ACL rupture (Figure 34-9*A, B,* and *C*).

Treatment

Nonoperative Management

- Rest, Ice, Compression, Elevation (RICE)
- Nonsteroidal antiinflammatory drugs (NSAIDs)
- Supervised physical therapy (PT) (see nonoperative rehabilitation section for details)
- Bracing: dependent on severity of injury and player demands
- Limited weightbearing: with higher-degree injuries only

Guidelines for Choosing Among Nonoperative Treatments

- Severity of injury: More severe injuries require more involved treatment, such as bracing, limited weightbearing, PT (see nonoperative rehabilitation section).

FIGURE 34-7. Valgus stress test with palpation for joint gapping.

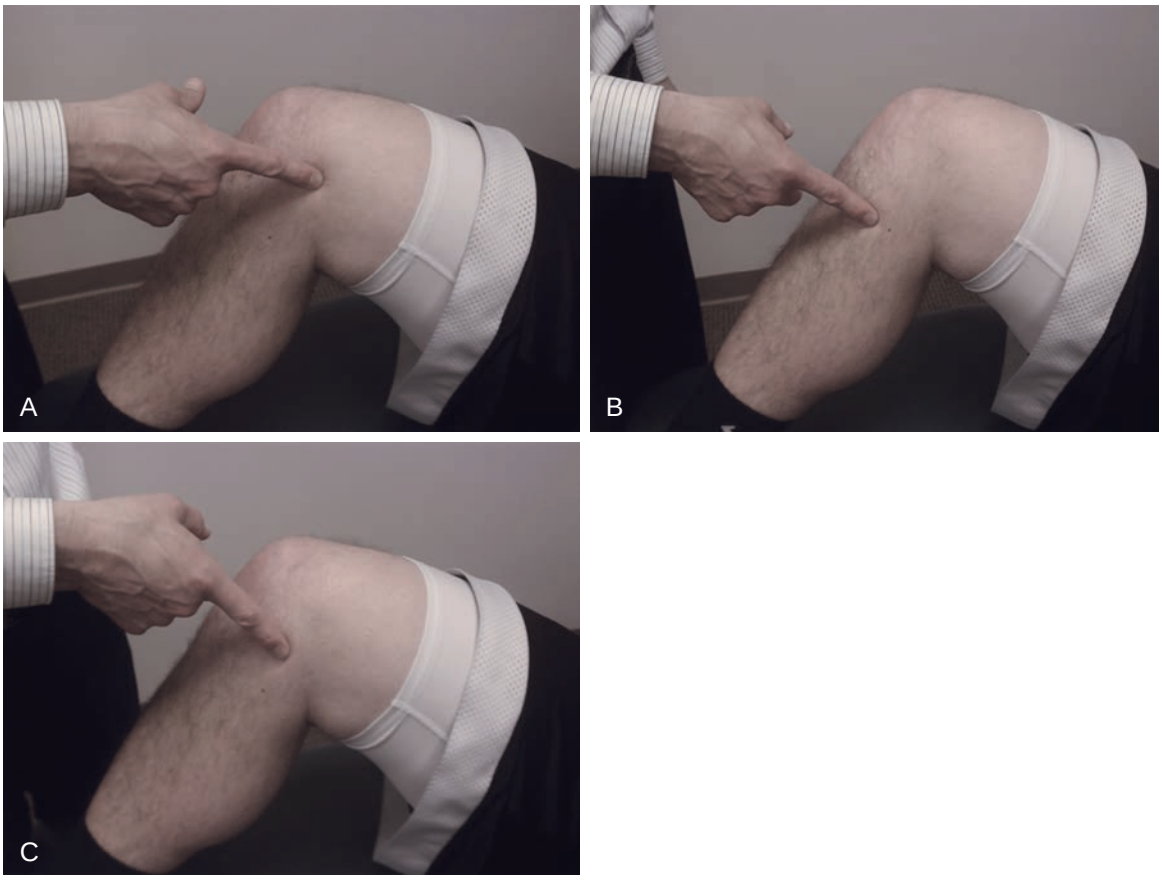

FIGURE 34-8. **A,** Palpation of proximal medial collateral ligament (MCL) insertion. **B,** Palpation of distal MCL insertion. **C,** Palpation of medial joint line.

- Sport demand: use of bracing for play, time until return to play

Surgical Indications

- Surgery is not indicated for most isolated MCL tears. Grades I and II isolated MCL injuries are always treated nonsurgically.
- Surgery is indicated in cases of combined injury, such as ACL/MCL.
- Surgery may be indicated in cases of persistent, significant laxity that prevents full return to sport. Surgery may also be appropriate in cases of persistent pain.

Aspects of History, Demographics, and Examination Findings that Affect Choice of Treatment

- Sport and position: Wide receivers and defensive backs will not return to play as quickly as linemen.
- Level of competition (recreational vs. collegiate/professional): Rehabilitation will likely be more aggressive with higher-level athletes, and return to participation will be quicker
- Severity of injury (grade I vs. III): Higher-grade injuries will require more care, progression to return to sport will be slower.
- Injury to other structures

Aspects of Clinical Decision Making When Surgery Is Indicated

- Complete ACL/MCL combined injury
- Possible as early treatment for complete proximal rupture or bony avulsion (confirmed by MRI)
- Failure of nonoperative treatment

Evidence

Battaglia MJ, 2nd, Lenhoff MW, Ehteshami JR, et al: Medial collateral ligament injuries and subsequent load on the anterior cruciate ligament: a biomechanical evaluation in a cadaveric model. *Am J Sports Med* 37:305–311, 2009.

The results of this cadaveric biomechanical study demonstrate the need for surgical intervention to treat combined MCL/ACL injuries.

Grant JA, Tannenbaum E, Miller BS, et al: Treatment of combined complete tears of the anterior cruciate and medical collateral ligaments. *Arthroscopy* 28:110–122, 2012.

In this systematic review, the authors compared five different treatment approaches for combined ACL/MCL injuries. The results demonstrate improved outcomes with delayed ACL reconstruction, which may allow the MCL to heal. (Level IV evidence)

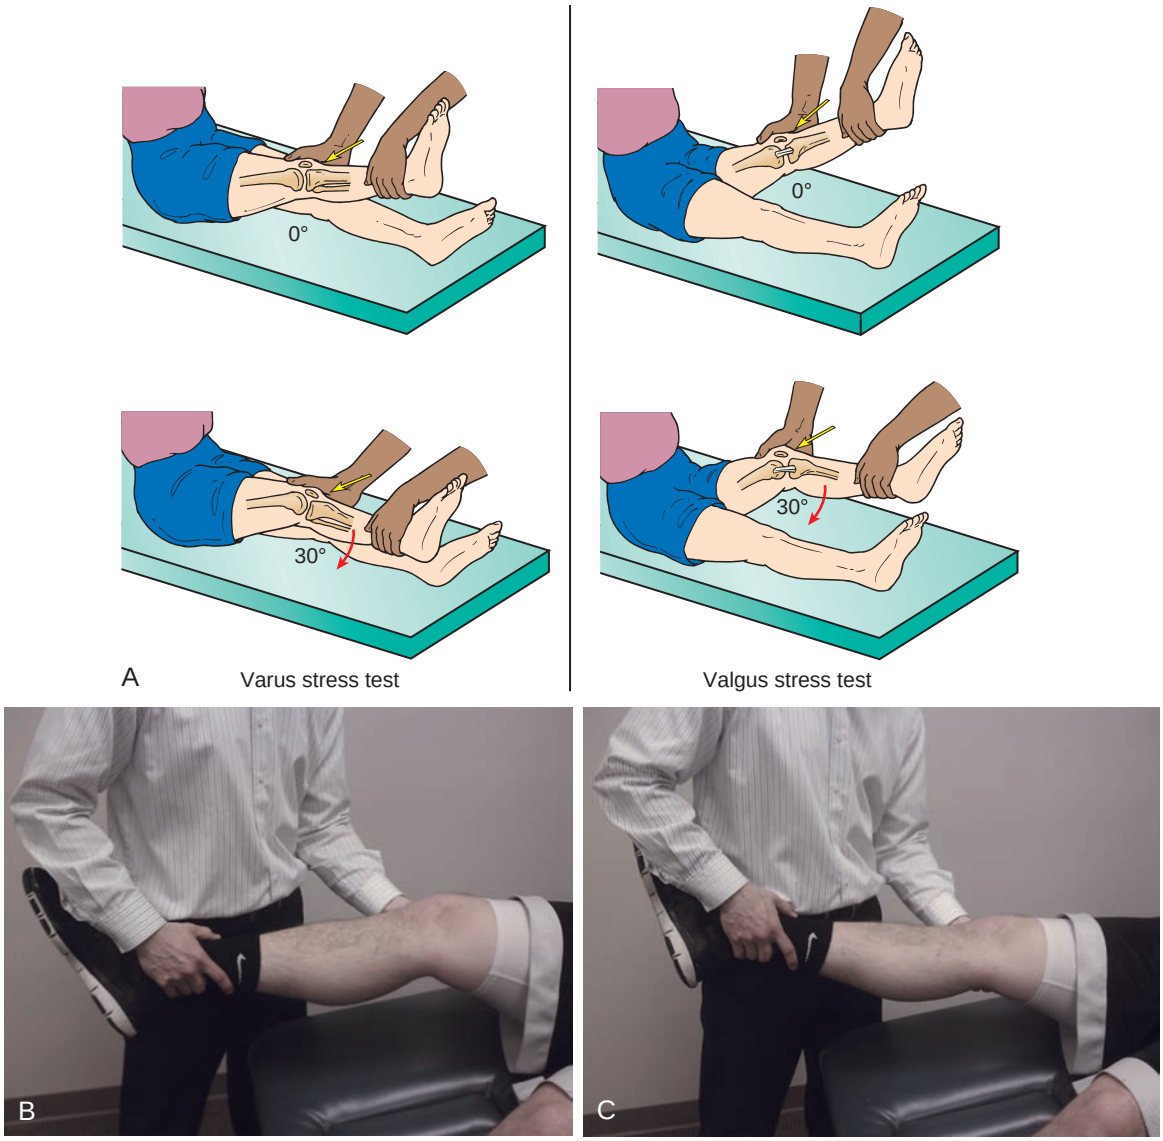

FIGURE 34-9. A, Valgus stress in flexion and extension. Stress in extension tests the medial collateral ligament and the posteromedial capsule. Stress in 30° of flexion tests only the medial collateral ligament. **B,** Valgus stress test in slight flexion. **C,** Valgus stress test in extension.

Hershman EB, Anderson R, Bergfeld JA, et al: An analysis of specific lower extremity injury rates on grass and FieldTurf playing surfaces in National Football League games: 2000–2009 seasons. *Am J Sports Med* 40:2200–2205, 2012.

In this epidemiology study, the authors reviewed game-related injury data during the time period stated and compared injury rates on FieldTurf surfaces versus grass. They found no significant difference when they compared MCL injury rates on grass versus FieldTurf surfaces. (Level II evidence)

Majewski M, Susanne H, Klaus S: Epidemiology of athletic knee injuries: a 10-year study. *Knee* 13:184–188, 2006.

In this epidemiology study, the authors reviewed 19,530 sport injuries over a 10-year period. Among all injuries, 39.8% were related to the knee, and 68.1% of those with knee injuries were men. Those 20 to 29 years of age comprised 43.1% of the sample. MCL sprains accounted for 7.9% of knee injuries. Judo and skiing were the activities that most commonly led to MCL injuries. (Level II evidence)

Marchant MH, Jr, Tibor LM, Sekiya JK, et al: Management of medial-sided knee injuries, part 1: medial collateral ligament. *Am J Sports Med* 39:1102–1113, 2011.

In this comprehensive review, the authors detail the anatomy, biomechanics, and mechanisms of injury; the imaging modalities to use; and nonoperative and operative treatment. (Level V evidence)

Multiple-Choice Questions

QUESTION 1. Which of the following is not an accurate list of factors that contribute to MCL injuries in the knee?

A. Valgus deformity, direct blow to the lateral knee, hip anteversion
B. Direct blow to the lateral knee, hip anteversion, synthetic playing surface
C. Valgus deformity, forced external rotation of the tibia, direct blow to the lateral knee
D. Previous injury, forced external rotation of the tibia, hip anteversion

QUESTION 2. Which of the following is not an appropriate initial treatment option for isolated MCL injuries of the knee?

A. Rest, Ice, Compression, Elevation (RICE)
B. NSAIDs and bracing
C. Surgical reconstruction
D. PT

QUESTION 3. When is surgery indicated as an initial treatment?

A. When there is a combined ACL/MCL injury
B. In cases of acute, severe pain and edema
C. In highly competitive, skilled athletes
D. None of the above

QUESTION 4. Which of the following are abnormal examination findings following isolated MCL injury of the knee?

A. Limited ROM, positive valgus stress test, anterior laxity, pain with palpation at the medial epicondyle
B. Limited ROM, positive valgus stress test, local edema, pain with palpation at the medial epicondyle
C. Limited ROM, positive valgus stress test, local edema, pain with palpation over the medial joint line
D. Limited ROM, anterior laxity, pain with palpation over the medial epicondyle, medial knee pain

QUESTION 5. Which of the following is the most common mechanism of injury for isolated MCL tears of the knee?

A. Direct blow to the lateral aspect of the knee with the foot planted
B. Forced external rotation of the tibia with the foot planted
C. Forced external rotation of the tibia with valgus force in an open kinetic chain
D. None of the above

Answer Key

QUESTION 1. Correct answer: **B** (see Pathophysiology)

QUESTION 2. Correct answer: **C** (see Treatment)

QUESTION 3. Correct answer: **A** (see Treatment)

QUESTION 4. Correct answer: **B** (see Clinical Presentation)

QUESTION 5. Correct answer: **A** (see Pathophysiology)

NONOPERATIVE REHABILITATION OF MEDIAL COLLATERAL LIGAMENT INJURIES

Robert J. Bradbury, BS, PT, OCS, and Michael J. Battaglia II, MD

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- Protect healing tissues
- Reduce/control edema
- Regain/maintain mobility and strength
- Maintain endurance
- Safe return to sports activities
- Medial collateral ligament (MCL) injuries of the knee are one of the most common injuries in sports and occur either in noncontact (pivoting) or, commonly, in contact sports caused by a direct blow to the lateral knee that results in valgus stress.
- Surgical reconstruction is almost never required, and therefore both accurate initial diagnosis and grading of the injury are critical prognostic factors in predicting return to play.
- Return to play can be recommended fairly early in grade I or II injuries and with treatment and bracing for up to 8 weeks in grade III tears.[1]
- A coordinated treatment plan developed by the physician and therapist will allow the athlete to have realistic expectations for progress.

Phase I (weeks 0 to 2)

Protection

- Crutches as needed to minimize gait deviations and weightbearing as tolerated
- Bilateral hinged brace, 0° to 30°
  - Grade I injuries typically do not require any bracing, because there is no joint laxity associated with this injury.
  - Grades II and III injuries do involve varying degrees of joint laxity[2] and need to be protected during the initial phases of healing.

Management of Pain and Swelling

- Rest, Ice, Compression, Elevation (RICE)
- Ultrasound: Nonthermal effects of ultrasound are most beneficial for tissue healing, so it is recommended that lower-duty cycles (i.e., pulsed ultrasound) be used for the treatment of acute injuries. (Daniel Lorenz, course notes for "Thermal Agents in Rehabilitation: Evidence-Based Update," 2010)
- Electrical stimulation
  - Transcutaneous electrical nerve stimulation (TENS)
    - TENS provides temporary pain relief
  - Interferential current (IFC)
    - IFC provides pain relief and also has antiinflammatory and edema reduction properties
  - High-voltage pulsed electrical stimulation (HVPS)
    - HVPS promotes soft-tissue healing
  - Neuromuscular electrical stimulation (NMES)
    - NMES may be used for quadriceps facilitation if the athlete has a decreased ability to fully contract the quadriceps musculature.
  - It is recommended that IFC or HVPS be used for treatment during this initial phase of rehabilitation.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Patellofemoral mobilizations

Soft-Tissue Techniques

- Gentle effleurage massage for edema reduction
- Cross-friction massage over healing tissue to promote tissue healing and optimize collagen organization

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Passive/active/active-assisted range of motion (PROM/AAROM/AROM) to tolerance
- Hamstrings
- Quadriceps
- Gluteals
- Hip adductors and abductors
- Gastroc-soleus
- The ability to fully stretch the musculotendinous unit will depend on the available ROM at the knee. As an example, if knee flexion ROM is limited caused by pain or to protect the healing MCL, the quadriceps muscles will not be able to be fully stretched.
- The MCL complex is reinforced by the pes anserine and by direct attachments to the vastus medialis and semimembranosus tendons.[3,4] It can be hypothesized that placing excess tension through these tendons may lead to increased strain on the healing MCL complex.

Other Therapeutic Exercises

- Total body strengthening (TBS)
  - The athlete should continue with the usual exercise regimen as much as possible to maintain conditioning for the specific sport as well as to promote strength in noninjured limbs.
  - Some lower-body training may have to be limited or modified. Trunk strength and core stabilization exercises should continue with planks in the frontal and sagittal planes, abdominal exercises, and spinal extensor strengthening.
- Total arm strengthening (TAS)
  - Upper-body training should continue with minimal restrictions. Care should be taken to protect the injured knee in the gym with careful positioning or use of a brace, using parameters based on grade of injury.
- Total leg strengthening (TLS)
  - Lower-body strengthening will be limited, depending on the severity of the injury.
    - Full lower-body strengthening workouts should be resumed as quickly as possible following grade I injuries.
    - Protective bracing should be used with weight training initially following grades II and III injuries.

TIMELINE 34-1: **Nonoperative Rehabilitation of MCL Injuries (Grade III)**

PHASE I (weeks 0 to 2)	PHASE II (weeks 2 to 4)
• Brace 0° to 30° • Physical therapy (PT) modalities • Effleurage massage for edema if needed • Patellar mobilizations • PROM/AROM/AAROM to tolerance • Lower-extremity flexibility exercises • OKC exercises to tolerance • CKC exercises as tolerated • TBS/TAS/TLS activities as recommended and tolerated	• Brace to 90° by 4 weeks • PT modalities • Deep transverse/cross-friction massage • Patellar mobilizations • Full ROM • Lower-extremity flexibility exercises • OCK exercises • CKC exercises with <90° flexion angles • SLS activities on unstable surfaces and/or with perturbations • Functional/sport-specific activities as tolerated • TBS/TAS/TLS activities as recommended and tolerated • Stationary bike

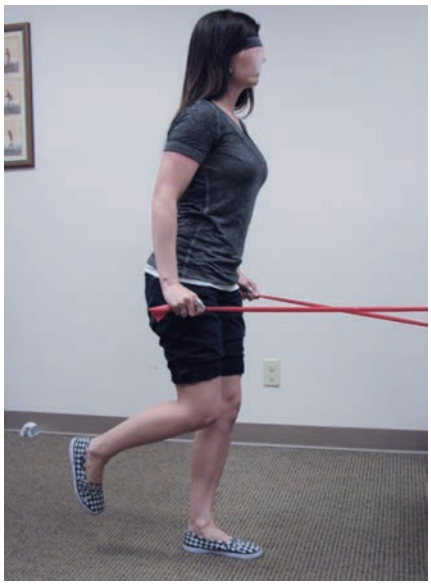

FIGURE 34-10. Single-limb stance with upper extremity perturbation.

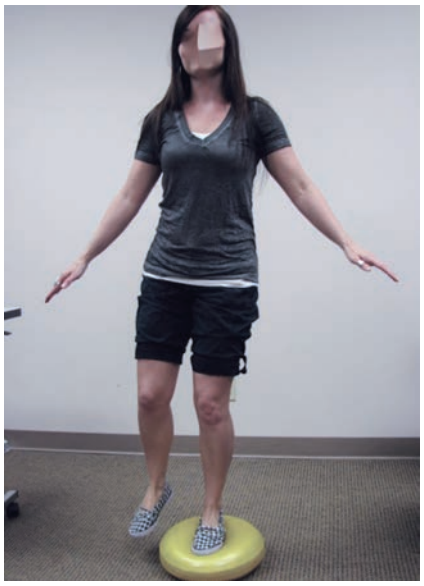

FIGURE 34-11. Single-limb stance on air disc for proprioception training.

As ROM improves and the athlete demonstrates good functional stability with single-limb stance activities on the involved lower-extremity, the brace may be discontinued during workouts.
- Safe closed-chain strengthening exercises of the contralateral limb should be initiated immediately following injury.

Activation of Primary Muscles Involved

- The quadriceps muscles, hamstrings, and gastocnemius directly affect the knee joint.
- Exercises to facilitate and maintain strength of these muscle groups are outlined below under open and closed kinetic chain (OKC/CKC) exercises.
- In addition to maintaining strength of the local musculature, it is imperative to maintain proximal strength and core stability. Weakness at the hip, specifically weakness of the hip extensors and abductors, creates unwanted joint reaction forces at the knee with weightbearing activities. During dynamic activities, weakness in hip abduction causes the knee to fall into a position of excess valgus, potentially placing excessive loads across the MCL.[5]

Sensorimotor Exercises

- Single-limb stance (SLS) activities
  - SLS should initially be performed on a stable surface with the eyes open. Once this is performed with ease, closing the eyes will eliminate visual input and provide greater challenge to the proprioception system.
  - SLS activities can be progressed by creating perturbations during the activity. Initially, these perturbations may be created by having the athlete perform an activity, such as upper movements with resistance or movements of the contralateral leg while standing on the injured leg (Figure 34-10). Perturbations may also be created manually by the therapist.

TIMELINE 34-1: **Nonoperative Rehabilitation of MCL Injuries (Grade III)** (Continued)

PHASE III (weeks 4 to 8)	PHASE IV (weeks 8 to 12)
• Brace for full ROM (per individual case) • PT modalities as needed • Patellar mobilizations • Tibiofemoral mobilizations if needed • OKC exercises without limitations • CKC exercises as tolerated • SLS activities: Increase amplitude and/or frequency of perturbations • Functional/sport-specific/agility activities to tolerance • Plyometrics • TBS/TAS/TLS activities as recommended and tolerated	• Brace for sports activities on an individualized basis • OKC exercises to preinjury level • CKC exercises without restrictions • Plyometric exercise to tolerance • Return to sports participation • TBS/TAS/TLS to preinjury levels

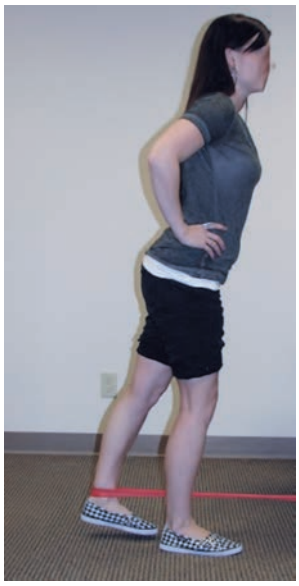

FIGURE 34-12. Closed kinetic chain extension. Involved lower extremity is the stance limb. Movement of the opposite lower extremity creates perturbations for the stance limb.

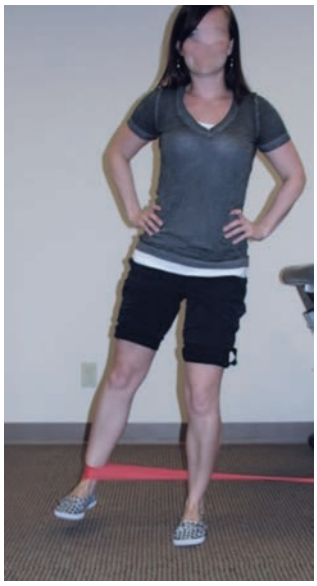

FIGURE 34-14. Closed kinetic chain abduction. Involved limb is the stance limb.

- Once the athlete demonstrates good dynamic control on a stable surface, these activities should be performed on an unstable surface such as Biomechanical Ankle Platform System (BAPS) board, an air disc, or foam mat, or Bosu ball (Figure 34-11).

OKC and CKC Exercises

- OKC
  - Three-way leg raises: Straight-leg raise (SLR), abduction, and extension. No adduction as this will place a valgus stress across the knee.
  - Short arc quadriceps/terminal knee extension (TKE): Full TKE may be restricted initially following grade III injuries.
  - Prone and standing hamstring curls
- CKC
  - Three-way leg raises with tubing/exercise band: abduction, extension, flexion (Figures 34-12 to 34-14)
  - Minisquats (Figure 34-15)
  - Leg press
  - Step-ups/step-downs (Figure 34-16)
  - Lunges (Figure 34-17)
  - Heel raises
  - Lateral steps with exercise band

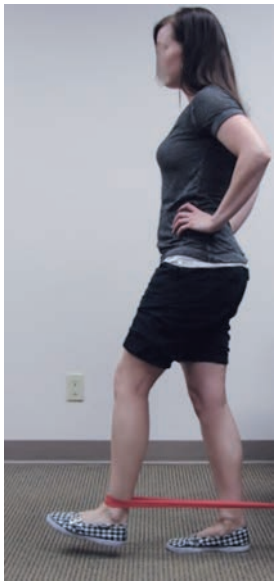

FIGURE 34-13. Closed kinetic chain flexion. Involved limb is weightbearing.

FIGURE 34-15. Forward stepdown.

- Lateral steps with squat (with band)
- Bridges/Swiss ball bridges
- Eccentric hamstrings

Techniques to Increase Muscle Strength, Power, and Endurance

- Strengthening exercises should be performed as noted above during Phase I of MCL rehabilitation.
- Muscular endurance training can be achieved with high repetitions during exercise and use of stationary cycling (when ROM allows) or an elliptical trainer.
- Power training should not be undertaken during Phase I.

Neuromuscular Dynamic Stability Exercises

- See Sensorimotor Exercises above

Functional Exercises

- Single-limb stance progression as outlined above
- Step-up/step-down
- Partial squats
- Lunges (Figure 34-18)

Sport-Specific Exercises

- Functional exercises can be performed or modified as needed to match the athlete's sport-specific needs.

Milestones for Progression to the Next Phase

- Full ROM with minimal to no pain
- Restoration of normal gait pattern

Phase II (weeks 2 to 4)

Protection

- Crutches as needed (wean as able): Use of crutches should be discontinued for injuries of all severities, and gait pattern should normal by 4 weeks postinjury.

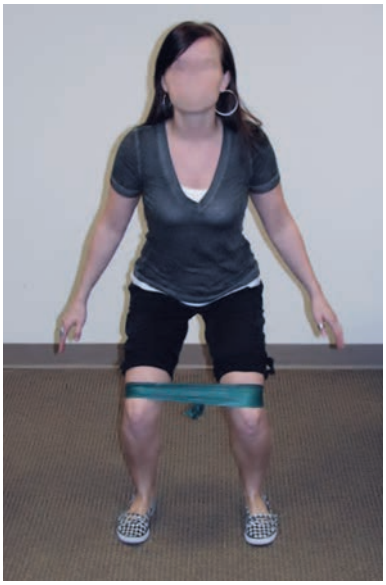

FIGURE 34-16. Minisquat with resisted abduction.

FIGURE 34-17. Lunge with resisted abduction.

TIMELINE 34-2: **Nonoperative Rehabilitation of MCL Injuries (Grade II)**

PHASE I (weeks 0 to 2)	PHASE II (weeks 2 to 4)	PHASE III (weeks 4 to 8)
• Brace 0° to 30° • PT modalities • Effleurage massage for edema if needed • Patellar mobilizations • PROM/AROM/AAROM to tolerance • Lower-extremity flexibility exercises • OKC exercises to tolerance • CKC exercises as tolerated • TBS/TAS/TLS activities as recommended and tolerated	• Brace for full ROM • PT modalities • Cross-friction massage • Patellar mobilizations • Full ROM • Lower-extremity flexibility exercises • OKC exercises • CKC exercises • SLS activities on unstable surfaces and/or with perturbations • Functional/sport-specific activities as tolerated • TBS/TAS/TLS activities as recommended and tolerated • Stationary bike	• Brace for full ROM (per individual case for sports activities) • PT modalities as needed • Tibiofemoral mobilizations if needed • OKC exercises without limitations • CKC exercises to preinjury levels • Return to sports participation • Plyometrics • TBS/TAS/TLS activities as recommended and tolerated

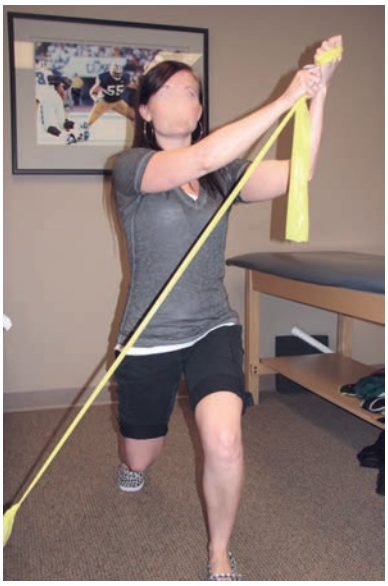

FIGURE 34-18. Lunge with upper-extremity resisted diagonal, perturbations created with upper-extremity movement.

- Bracing may be continued as needed. If continued bracing is required, full ROM should be allowed. Bracing is often an individual choice with MCL injuries, and continued use of a brace depends on the athlete's sport, position, and mobility required. For example, in football, a lineman will likely continue protective bracing, whereas receivers or defensive backs may choose not to wear a brace when returning to sports activity.

Management of Pain and Swelling

- Use of modalities can be continued as needed for pain control and decreased inflammation.

Techniques for Progressive Increase in ROM

Manual Therapy Techniques

- Patellofemoral mobilizations as needed
- Tibiofemoral mobilizations may be used at this stage if there is persistent stiffness in end-range flexion or extension.
- Anterior glides of the tibia on the femur will assist in improving knee-extension ROM.
- Posterior glides will improve flexion ROM in cases of persistent joint stiffness.[6]
- Caution should be used with grade III injuries, as tibiofemoral mobilizations may create unwanted strain to other ligaments, such as the anterior cruciate ligament (ACL), especially if mobilizations are performed in slight flexion.[7]

Soft-Tissue Techniques

- Retrograde effleurage should continue in cases of persistent edema.
- Cross-friction massage should be continued over the injured portion of the ligament to promote ideal collagen construction and repair.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Flexibility exercises for the lower extremity should be performed without limitations, and ROM should be increased to equal that of the contralateral limb.
- In cases of grade III injuries adductor stretching may need to be progressed more slowly, and full ROM may not be achieved until Phase III of rehabilitation. Pain is to be used as a guide.

Other Therapeutic Exercises

- TBS: During Phase II, TBS and core training should return to full level for grades I and II injuries. For those with grade III injuries, TBS should continue to be gradually progressed to the athlete's normal level of training with use of a brace if needed.
- TAS should be performed without restrictions for all grades of injury.
- TLS should be returned to the athlete's normal level of training. Deep squats, lunges, or full-range leg presses should be avoided in cases of grade III injuries.

Activation of Primary Muscles Involved

- Exercises that specifically affect the muscles that perform knee motions should be progressed to normal levels. See Phase I above for specific exercises.

Sensorimotor Exercises

- SLS stance activities should be progressed at this stage, with perturbations increasing in amplitude and/or frequency.
  - As discussed under this topic for Phase I of rehabilitation, perturbations may be created manually by the therapist, by the athlete via movements of other limbs, or with the use of exercise bands, tubing, or resistance cables.

OKC and CKC Exercises

- OKC exercises should continue as outlined under Phase I.
- Adduction SLR may be added for all athletes.
- For athletes with grade III injuries, any weight added for adduction SLR should be placed proximal to the knee.
- Full-ROM quadriceps isotonic exercises may also be initiated at this stage.
- CKC exercises may be performed with larger ROM as pain allows.
- Flexion angles greater than 90° should be avoided in cases of grade III injuries.
- Exercises should be performed without use of protective bracing if the athlete demonstrates normal functional stability and full confidence with CKC activities.

Techniques to Increase Muscle Strength, Power, and Endurance

- Clean
- Snatch

- Push–pull
- Squats
- Initiate running program (grade II and III injuries)
- Strengthening exercises should be progressed to normal levels during this phase of rehabilitation.
- Resistance and speed of movement should be increased to tolerance.
- To maintain and/or improve muscular endurance, aerobic-type exercises can be progressed by increasing resistance, velocity, and/or duration.

Neuromuscular Dynamic Stability Exercises

- See Sensorimotor Exercises

Plyometrics

- Bilateral hopping on level surface
  - During plyometric and jumping activities, close attention must be paid to landing mechanics to ensure proper lower-extremity alignment to avoid excessive valgus forces through the knee. Sufficient hip and core strength is required to maintain proper positioning during eccentric landing. Foot and ankle mechanics must also be assessed for excessive pronation with landing, as this mechanical fault may lead to excessive valgus stress at the knee.[5]

Functional Exercises

- Functional exercises should be continued as listed under Phase I and progressed as the athlete tolerates. These exercises should become more sport-specific as tolerance improves.
- Athletes with grade II injuries are likely ready or close to ready to return to full sports activity toward the end of Phase II, so the program will consist mostly of sport-specific exercises.
- For athletes with more severe injuries, lower-level, uniplanar functional exercises may have to be continued for a longer period of time.

Sport-Specific Exercises

- See Sensorimotor Exercises and Functional Exercise sections above.

Milestones for Progression to the Next Phase

- Full ROM without pain
- No increase in swelling with light activity
- No functional instability

Phase III (weeks 4 to 8)

Protection

- Crutches should no longer be used.
- Bracing may be continued based on individual preferences.

Management of Pain and Swelling

- Ice and IFC electrical stimulation may be continued in cases of persistent edema.
- All other modalities should be discontinued during this phase of recovery.

Techniques for Progressive Increase in ROM

Manual Therapy Techniques

- Tibiofemoral mobilizations
  - Anterior or posterior glides may be used at end ranges of physiologic ROM if there is any joint stiffness.
  - Rotational mobilizations may be required to restore concomitant external rotation at TKE or internal rotation with end-range flexion.[6]

Soft-Tissue Techniques

- Cross-friction massage may be continued over the healing ligament and should be performed directly over the site of the tear.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Lower-extremity stretching should continue without restrictions and at this point should be at preinjury levels.
- Proprioceptive neuromuscular facilitation (PNF) may be used for dynamic stretching. PNF is also facilitatory and will improve neuromuscular responses to dynamic loads across the lower extremity. Hip and knee patterns are most effective in cases of injuries to the knee.
- Dynamic stretching or warmup should be performed prior to sport activities. The Sportmetrics warm-up for injury prevention and performance program and Santa Monica sports medicine research foundation prevent injury, enhance performance are good examples of a thorough dynamic stretching routine for the lower extremities.

Other Therapeutic Exercises

- At this stage of recovery, exercise regimens should be at preinjury levels for athletes with any severity level of isolated MCL injury.
- TBS, TAS, and TLS exercises can be performed without restrictions; however, athletes with more severe injuries may wish to continue to wear a brace when performing dynamic multiplanar activities.

Activation of Primary Muscles Involved

- Training of local musculature is now unrestricted, and all exercises should be performed to the athlete's tolerance and at full speed if not already done.

Sensorimotor Exercises

- Sensorimotor exercises should be performed to tolerance with use of protective bracing if needed.

OKC and CKC Exercises

- Exercise regimens should return to preinjury levels during this phase of rehabilitation.

Techniques to Increase Muscle Strength, Power, and Endurance

- As stated under the previous topic, at this point following injury, there are no restrictions on exercise.

Neuromuscular Dynamic Stability Exercises

- Dynamic stability exercises should continue to be progressed to meet the athlete's sport-specific demands.

Plyometrics

- Box jumps
- Zig-zag hops
- Squat jumps
- Split jumps
- Plyometric exercises can be progressed as the athlete tolerates. Jumping activities may also be progressed to unilateral take-offs and landings with the involved lower extremity.

Functional Exercises

- Running and agility training should continue to be progressed.
- Agility drills should be specific to the athlete's sport.
- Some athletes with grade III injuries will return to live practice activities at this stage, and most athletes with grade II MCL tears will already have returned to sports participation.

Sport-Specific Exercises

- See above.

Milestones for Progression to the Next Phase

- Successful completion of a running program
- 90% of normal strength in isokinetic testing or passing grade on functional testing

Phase IV (weeks 8 to 12)

Protection

- Protective bracing is no longer required; however, some athletes will continue to use a hinged knee brace.
- In cases where external support is needed but use of a bulky brace is not practical, tape may be applied to provide support to the medial knee. The reader is referred to athletic training textbooks and taping manuals for further information on taping techniques.

Management of Pain and Swelling

- Ice can continue to be applied after exercise as needed.
- IFC electrical stimulation may be used in cases of edema following activity.

Techniques for Progressive Increase in ROM

Manual Therapy and Soft-Tissue Techniques

- Manual therapy and soft-tissue techniques are no longer required and should be discontinued.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- The athlete is now able to perform their normal stretching routine and may do so independently or with a trainer.

Other Therapeutic Exercises

- There are no restrictions to exercise.
- Exercise programs should return to preinjury levels, and the athlete may fully participate in team's regular training routine.
- The athlete should return to full sports participation during this stage of rehabilitation.

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention

- Surgical treatment is not indicated in cases of isolated grade I or II MCL injuries.
- It has been demonstrated that joint laxity may persist following tissue healing in grade III injuries. Despite persistent joint laxity, functional outcomes are similar with operative vs. conservative care. The authors choose to treat all isolated grade III injuries nonoperatively; however, surgical repair may be required in cases of chronic instability or persistent pain.
- Surgery is required in cases of combined injuries. Treatment of combined injuries is beyond the scope of this chapter and thus is not discussed here.

Milestones and Criteria-Based Rehabilitation Guidelines to Progress to Sport-Specific Training and Conditioning

- As discussed under Phase III, the athlete must successfully complete a running program without increased pain, swelling, or sense of instability.

- Isokinetic strength testing
  - In order for the athlete to return to participation in his or her sport, they either must be at 90% of normal or of the contralateral limb or they must achieve a passing score with functional testing
- Return to sport participation should be graded and incremental. After demonstrating readiness to progress to sports activity, the athlete should participate in practice drills. If participation in basic practice drills is successful, the athlete may participate in team scrimmage activities. If there is no adverse reaction with participation in scrimmage, the athlete may return to full competition.

Tips and Guidelines for Transitioning to Performance Enhancement

- Progression to performance enhancement should occur during Phase III or IV of rehabilitation. At this stage of recovery, physiologic tissue repair is stable, ROM should be full, and strength should be normal. Therapy sessions may continue less frequently, as needed, to monitor the athlete's status and progress.

Performance Enhancement and Beyond Rehabilitation: Training/Trainer and Optimization of Athletic Performance

- Performance enhancement can be achieved by progressing agility activities, such as T-runs, side-step drills, or agility ladder exercises. Performance enhancement activities should be specific to the athlete's sport-specific demands. Speed, agility, and power training should be employed and tailored to match the athlete's needs.

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Normal strength (isokinetic)
- Completion of running and/or agility program
- Passing score on functional testing

Evidence

Battaglia MJ, 2nd, Lenhoff MW, Ehteshami JR, et al: Medial collateral ligament injuries and subsequent load on the anterior cruciate ligament: a biomechanical evaluation in a cadaveric model. *Am J Sports Med* 37:305–311, 2009.

This biomechanical evaluation provides information on excess strain to other knee ligaments in the presence of combined injuries. This information can be used by clinicians to minimize possible iatrogenic injuries during rehabilitation.

Hengeveld E, Banks K, editors: *Maitland's peripheral manipulation*, ed 4, New York, Elsevier, 2005, Elsevier.

This textbook provides rationale and technique instruction for passive mobilization of peripheral joints.

Mandelbaum B, Silvers HJ, Watanabe DS, et al: Effectiveness of a neuromuscular and proprioceptive training program in preventing anterior cruciate ligament injuries in female athletes: 2-year follow-up. *Am J Sports Med* 33:1003–1010, 2005.

In this nonrandomized prospective study, the authors compared injury rates among teenage girl soccer players participating in traditional warmups versus sport-specific training. Athletes participating in sport-specific training had a significantly lower incidence rate of ACL injuries.

Marchant MH, Jr, Tibor LM, Sekiya JK, et al: Management of medial-sided knee injuries, part 1: medial collateral ligament. *Am J Sports Med* 39:1102–1113, 2011.

This article is focused on the anatomy and biomechanics of the medial knee structures and includes a review of nonoperative and operative treatments.

Phisitkul P, James SL, Wolf BR, et al: MCL injuries of the knee: current concepts review. *Iowa Orthop J* 26:77–90, 2006.

This article reviews the anatomy and biomechanics of the MCL and the classification systems for MCL injuries.

Powers CM: The influence of abnormal hip mechanics on knee injury: a biomechanical perspective. *J Orthop Sports Phys Ther* 40:42–51, 2010.

This clinical commentary and review provides evidence for incorporating proximal hip and trunk strengthening in rehabilitation of various knee injuries, including medial soft-tissue restraints. (Level V evidence)

Reider B, Sathy MR, Talkington J, et al: Treatment of isolated medial collateral ligament injuries in athletes with early functional rehabilitation: a five-year follow-up study. *Am J Sports Med* 22:470–477, 1994.

This prospective study demonstrated that early functional rehabilitation (EFR) is safe and effective compared to immobilization or operative treatment and that athletes participating in EFR returned to sports activities earlier than those treated with casting or surgical repair. This was the first article to provide long-term follow-up after isolated MCL injury.

Multiple-Choice Questions

QUESTION 1. Which of the following is the most effective type of electrical stimulation to control pain and edema following an acute MCL injury?

A. Neuromuscular electrical stimulation (NMES)
B. Interferential current (IFC)
C. High-voltage pulsed electrical stimulation (HVPS)
D. B and C

QUESTION 2. Which of the following is not an appropriate OKC exercise to perform during Phase I of rehabilitation following an acute MCL injury?

A. Straight-leg raise
B. Hip adduction
C. Short-arc knee extensions
D. Prone hamstring curls

QUESTION 3. Single-limb stance activities may be performed with perturbations created by the athlete or therapist. These activities can be progressed by increasing which of the following?

A. Amplitude and/or frequency
B. Amplitude only
C. Frequency only
D. None of the above

QUESTION 4. An athlete must meet which of the following milestones to return to sport following an isolated MCL injury of the knee?

A. Normal strength, completion of a running program, passing score on a functional testing protocol
B. Full ROM, normal strength, able to run without pain
C. Normal gait pattern, passing score with functional testing, no joint laxity
D. No functional instability, normal strength, completion of a running program

QUESTION 5. MCL injuries are treated nonoperatively in most cases, but surgical intervention may be required for which of the following reasons?

A. Persistent pain
B. Chronic instability
C. Combined injuries
D. All of the above

Answer Key

QUESTION 1. Correct answer: **D** (see Phase I: Treatment for Pain and/or Swelling)

QUESTION 2. Correct answer: **B** (see Phase I: OKC and CKC exercises)

QUESTION 3. Correct answer: **A** (see Phase II: Sensorimotor Exercises)

QUESTION 4. Correct answer: **A** (see Phase IV)

QUESTION 5. Correct answer: **D** (see Criteria for Abandoning Rehabilitation)

POSTOPERATIVE REHABILITATION AFTER REPAIR OR RECONSTRUCTION OF THE MEDIAL COLLATERAL LIGAMENT

Timothy S. Mologne, MD, and Molly Van Zeeland, DPT

Indications for Surgical Treatment

- Acute repair
  - Intraarticular entrapment of one of the ends of the ligament
  - Displaced bony avulsion of the medial collateral ligament (MCL)
  - Complete MCL tear in patients with valgus alignment
  - Associated tibial plateau fracture
  - Anteromedial rotatory instability
  - Complete tibial side avulsion in cutting sport athletes
  - In conjunction with anterior or posterior cruciate ligament (ACL or PCL, respectively) reconstruction when there is valgus laxity in full extension
- MCL reconstruction
  - Symptomatic chronic valgus instability

Brief Summary of Surgical Treatment

Major Surgical Steps

- Acute repair
  - Location of the tear and assessment of tissue quality and damage are assessed by examining a preoperative magnetic resonance imaging scan
  - Supine position
  - Tourniquet on proximal thigh
  - Arthroscopy is performed to assess for intraarticular pathology and to assess the deep MCL and the meniscocapsular junction.
  - Incision from the medial proximal tibia to the medial epicondyle
  - For isolated proximal or distal repairs, a more limited incision can be utilized.
  - The sartorial fascia is incised to expose the torn ligamentous tissue. Distally, the ligament is deep to the pes anserine tendons.
  - All torn tissue is repaired, including peripheral meniscus tears, posterior oblique ligament tears, meniscofemoral ligament tears, and meniscotibial ligament tears. Suture anchors are utilized in some cases.
  - Tibial avulsion injuries are repaired to the tibia using suture anchors or screws with soft-tissue washers (Figure 34-19*A,B*).
  - Femoral avulsion injuries are repaired anatomically using suture anchors or screws and soft-tissue washers (Figure 34-19*C*).
- For patients with chronic valgus laxity or those found to have inadequate tissue to repair primarily, an augmentation or reconstruction is performed (Figure 34-19D).
  - Standing hip-to-ankle alignment x-rays should be obtained to assess for valgus alignment. If present, a varus-producing distal femoral osteotomy should be performed before MCL reconstruction.
  - Reconstruction can be performed with autograft or allograft tissue. The authors' preference is the ipsilateral semitendinosis tendon.

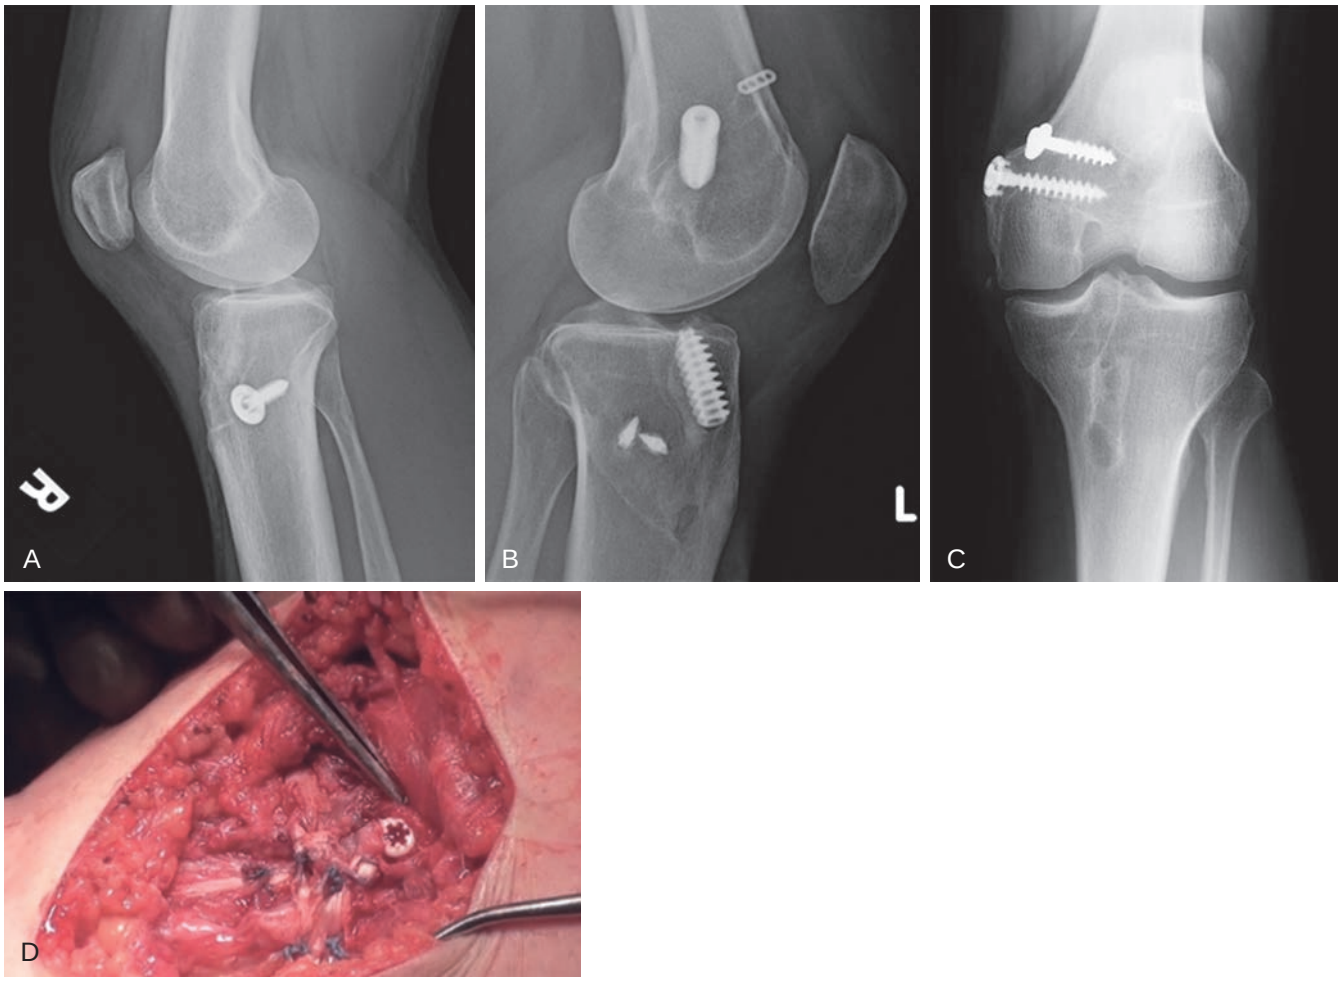

FIGURE 34-19. A, Distal MCL repair using a screw and washer in a patient who also underwent an ACL reconstruction. **B,** Repair of a distal MCL detachment using suture anchors in a patient following a knee dislocation. Other metallic implants are fixations for ACL and PCL reconstruction. **C,** Repair of a proximal MCL detachment using a screw and spiked washer. This patient also underwent reconstruction of the ACL and PCL. **D,** MCL reconstruction using an autogenous semitendinosis tendon graft. (*Solid black arrow:* Interference screw holding the tendon graft in a tunnel in the medial epicondyle. *Dashed black arrow:* Anterior limb of the graft reconstructing the superficial MCL. *White arrow:* Posterior limb of the graft reconstructing the posterior oblique ligament.)

- An open-looped tendon stripper is used to harvest the semitendinosus tendon, leaving the distal insertion/attachment intact.
- A pin is drilled into the medial epicondyle at the MCL origin, and ligament isometry is assessed by taking the knee through a range of motion (ROM). The pin is moved until isometric testing reveals less than 2 mm of excursion.
- A 7- to 8-mm socket is drilled to a depth of 30 mm at the isometric spot.
- The semitendinosis tendon is looped onto itself and sutured together for 30 mm.
- The loop is pulled into the femoral socket by passing a Beath pin across the knee and using a traction suture to pull and tension the semitendinosis tendon.
- The knee is placed at 30° of flexion, and varus stress is applied.
- The graft is fixated in the femoral tunnel using an absorbable interference screw.
- The free limb of the graft is then tensioned distally and posteriorly.
- If enough length is present, the free limb can be fixated to the posterior and proximal tibial using a screw with a soft tissue washer. If not, it is sutured to the semimembranosis.

Before Surgery: Overview of Goals, Milestones, and Guidelines[1]

GUIDING PRINCIPLES OF POSTOPERATIVE REHABILITATION

- The same protocol is used for MCL repair and MCL reconstruction.
- Repair of femoral avulsions of the MCL are associated with stiffness and loss of motion due to capsular adhesions. Aggressive motion exercises and overpressure can help prevent this problem.
- Understand the anatomic structures repaired and which positions and activities stress the healing structures.
- Isolated MCL repair or reconstruction is rare; the evidence suggests that surgical intervention provides no benefits over conservative management in most cases. MCL repair is often performed in patients with multiple ligament involvement, and, as a result, rehabilitation is usually slower than the timeline presented. Clinicians must pay particular attention to the milestones during each stage of rehabilitation and be careful not to progress patients too early.
- Studies have shown that epiphyseal injuries are frequently associated with ligamentous injuries in children. Clinicians must carefully monitor these individuals for development of genu valgus deformities after MCL injuries.[1]

[1]*Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

Phase I (days 0 to 14): Immediate Postoperative Period

Clinical Pearls

- It is important to avoid aggressive ROM exercises for the first 3 weeks postoperatively to avoid placing tension on the repaired ligament or graft.
- Research has shown that knee stiffness after medial repair/reconstruction is one of the most common complications; therefore, initiation of ROM exercises between 30° and 90° is necessary and should be strongly encouraged as part of a home exercise program (HEP) to avoid capsular adhesion formation.[2,3]
- It is imperative to control swelling during the first two phases of rehabilitation, as research has proven that swelling causes notable quadriceps inhibition and reduces quadriceps electromyographic activity with as little as 10 ml of fluid.[4]

Goals

- Decrease pain and inflammation
- Protect the repaired structures
- Avoid scar hypertrophy
- Avoid knee capsular adhesion formation
- Prevent quadriceps atrophy

Protection

- Hinged knee ROM brace with thigh and leg extensions limited to 30° to 90° knee flexion for the first 3 weeks.[2,5] Brace must be used at all times, including during HEP and at night.
- Non–weightbearing (NWB) using an assistive device (most often crutches) must be utilized for ambulation for the first 3 weeks postoperatively.[2,5]

Management of Pain and Swelling

- Cryotherapy for 20 to 30 minutes every hour during the first week[4]
- Interferential current (IFC) or transcutaneous electrical nerve stimulation (TENS) for pain
- Oral pain medications
- Leg elevation
- Compression
- High-voltage galvanic stimulation

Techniques for Progressive Increase in ROM

Manual Therapy Techniques

- ROM limited to 30° to 90° knee flexion for 3 weeks.
- ROM exercises may include passive ROM, active assisted ROM, and active ROM (PROM/AAROM/

AROM as tolerated and should be performed frequently to facilitate scar remodeling and to prevent adhesion formation.
- Patellar mobilization all directions to prevent adhesion formation and hypomobility
- Cephalic glides to promote knee extension and caudal glides to promote knee flexion

Soft-Tissue Techniques

- Cross-friction massage to MCL insertions to break up scar tissue/adhesions if limiting motion or flexibility
- Soft-tissue mobilization of quadriceps and hamstring musculature
- Scar mobilization when incision is healed

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Quadriceps and hamstring stretching per ROM guidelines
- Initiate early ankle ROM exercises and gastrocnemius/soleus stretching using a belt or towel.
- Static stretching should be held for 30 seconds for younger patients and 60 seconds for patients older than 60.

Other Therapeutic Exercises

- Ankle pumps every hour
- Hamstrings and quadriceps isometric contractions at 30°, 50°, 70°, and 90°
- Cocontractions of quadriceps and hamstrings
- Hamstring and quadriceps isotonics per ROM guidelines without resistance
- Hip three-way straight leg raise (SLR) (avoid adduction to avoid valgus stress at the knee)
- Core stability training
- Upper-body exercises (UBEs) are permitted, provided that they comply with weightbearing (WB) status and ROM guidelines.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- It is important to begin isometric quadriceps strengthening on postoperative day 1 to minimize muscle atrophy.
- Neuromuscular electrical stimulation (NMES) may also be used to facilitate or assist with quadriceps activation and minimize muscle inhibition due to effusion for up to 8 h/day.[4]

Neuromuscular Dynamic Stability Exercises

- Begin with isometric quadriceps postoperative day one.
- Progress to SLR with brace once neuromuscular control is obtained.
- NMES may be used to facilitate or assist with quadriceps muscle activation.
- Biofeedback may also be useful during this phase.

Milestones for Progression to the Next Phase

- Good quadriceps set
- ROM 30° to 90°
- Controlled knee pain and swelling

Phase II (weeks 2 to 4 postoperatively)

Clinical Pearls

- It is essential to avoid hyperextension during this phase to minimize tension on the repair/graft.
- It is critical that the patient avoid externally rotating the hip on the surgical side in an attempt to unload the limb. This rotation creates a valgus moment at the knee and puts tension on the graft/repair.[3]
- Research has shown that knee proprioception and kinesthesia are disrupted after injury and that mechanoreceptors within collateral ligaments and the joint capsule are often damaged, which will slow the individual's response to perturbations.[6] Balance and proprioception exercises should be started shortly after the patient begins full weight bearing (FWB).

Goals

- Achieve 0° to 90° knee ROM
- Normal gait mechanics with weightbearing as tolerated (WBAT) and use of crutches
- SLR with no extensor lag

Protection

- Hinged brace with 0° extension stop to avoid hyperextension
  - Brace should be locked at 0° extension for ambulation and sleeping until the patient has good quadriceps control. Brace should be worn at all times for 8 weeks postoperatively.
- Week 3: The patient may begin WBAT with the use of crutches and hinged brace with 0° extension stop once full knee extension has been achieved and there is no evidence of quadriceps lag.[2,5,6]

Management of Pain and Swelling

- Cryotherapy
- IFC
- TENS

Techniques for Progressive Increase in ROM

Manual Therapy Techniques

- Continue PROM/AAROM/AROM exercises: Extension exercises may include towel extension or prone hangs in hinged brace with 0° extension stop.

- Flexion exercises may include wall slides, heel slides, and seated AAROM.
- Patellar mobilizations to increase ROM as needed
- Grades I and II tibiofemoral joint mobilizations as needed

Soft-Tissue Techniques

- Cross-friction massage to MCL insertions to break up scar tissue/adhesions if limiting motion or flexibility is present.
- Soft-tissue mobilization of quadriceps and hamstring musculature
- Scar mobilization when incision is healed

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Ankle ROM and gastrocnemius/soleus stretching is encouraged and can be done as part of the HEP.
- Continue quadriceps and hamstring stretching per ROM.

Other Therapeutic Exercises

- Hamstring isotonics per ROM
- Quadriceps isotonics per ROM
- Short-arc quadriceps with bolster
- Progressive hip three-way SLR (avoid adduction); progress 1 to 2 lb/wk
- Controlled upper-body strengthening
- Core stability exercises (e.g., hooklying transverse abdominus recruitment exercises, double-leg bridging)

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Focus should be on regaining full quadriceps control so progression to FWB status can be done safely.

Sensorimotor Exercises

- Controlled weightshifting
- Single-leg balance

Open and Closed Kinetic Chain Exercises

- Closed kinetic chain (CKC)
  - Leg press/total gym: 0° to 45° ROM to protect the patellofemoral joint (begin exercise at no more than one-fourth body weight and slowly progress the patient as tolerated.)
  - Double-leg bridges
- Open kinetic chain (OKC)
  - Short-arc quadriceps with bolster: Progress 1 to 2 lb/wk
  - Three-way SLRs: Progress 1 to 2 lb/wk
  - Clam exercise with Thera-Band

Techniques to Increase Muscle Strength, Power, and Endurance

- Upper-body strengthening permitted in controlled environment and may include UBEs, machine weights, and free weights

Neuromuscular Dynamic Stability Exercises

- Manual rhythmic stabilization of trunk and core

Functional Exercises

- Continue gait training with crutches to normalize gait pattern with gradual progression to FWB.

Milestones for Progression to the Next Phase

- Knee ROM 0° to 90°
- Controlled knee pain/effusion

TIMELINE 34-3: **Postoperative Rehabilitation After Isolated MCL Repair or Reconstruction**

PHASE I (weeks 0 to 2)	PHASE II (weeks 2 to 4)
• Hinged brace with leg and thigh extensions limited to 30°–90° knee flexion • Physical therapy (PT) modalities (NMES for quadriceps, TENS, cryotherapy) • NWB for first 3 wk • Ambulate with bilateral crutches • PROM/AAROM/AROM exercises 5 to 8 times/day • TBS/TAS/TLS activities as recommended and tolerated • Three-way SLR: Avoid adduction • Isometric quadriceps/hamstrings postoperative day 1	• Hinged brace: 0° extension lock and open flexion • WBAT at 3 wk if full knee extension achieved • Single-leg balance/proprioception training • Wk 5: D/C crutches when good quadriceps control and normal gait achieved • ROM wk 3: 0°–90° • ROM wk 4: 0°–110° • ROM wk 6: 0°–120° • TBS/TAS/TLS activities as recommended and tolerated • Wk 5: Standing three-way SLR (avoid adduction) • Wk 5: Bike without resistance for ROM • CKC exercises as recommended

- Ambulation with normal gait pattern using bilateral crutches and FWB
- No quadriceps lag with SLR

Phase III (weeks 4 to 8 postoperatively)

Clinical Pearls

- Research has shown that individuals have a tendency to unload their surgically treated extremity for up to 6 months after knee surgery; therefore, progression from double-leg exercises to single-leg exercises should be begun as soon as possible during this phase.
- It is important that all exercises be performed with careful monitoring of good lower-extremity (LE) control and knee alignment.
- Patients should continue to avoid resisted hip adduction exercises and external rotation of the tibia to avoid stress on the repair/graft.
- Recurrent pain and swelling are signs of too-rapid progression during this phase.

Goals

- Full knee ROM
- Ambulate with normal gait pattern without crutches
- Good quadriceps control

Protection

- Hinged brace with 0° extension stop to avoid hyperextension (should be worn at all times for 8 weeks postoperatively)
- Week 4: Begin ambulation with FWB and hinged brace with 0° extension stop and bilateral crutches.
- Week 5: Discharge Crutches when patient has good quadriceps control and is able to ambulate with normal gait mechanics

Management of Pain and Swelling

- Cryotherapy
- IFC
- TENS

Techniques for Progressive Increase in ROM

Manual Therapy Techniques

- Continue ROM exercises as recommended above
- Week 5: Begin bicycle exercise for ROM with no resistance (brace can be removed at this point)
- Patellar mobilizations as needed
- Grades II and III tibiofemoral joint mobilizations as needed

Soft-Tissue Techniques

- Cross-friction massage to MCL insertions to break up scar tissue/adhesions if limiting motion or flexibility
- Soft-tissue mobilization of quadriceps and hamstring musculature
- Scar mobilization when incision is healed

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Ankle ROM and gastrocnemius/soleus stretching is encouraged and can be done as part of the HEP.
- Quadriceps and hamstring stretching

TIMELINE 34-3: **Postoperative Rehabilitation After Isolated MCL Repair or Reconstruction** (Continued)

PHASE III (weeks 4 to 8)	PHASE IV (weeks 8 to 12)	PHASE V (weeks 12 to 24)
• DC hinged brace for activities of daily living at 8 wk • Functional Hinged Brace for HEP/return to sport for 12–18 mo postoperatively • PT modalities as needed • Full knee ROM at wk 8 • ROM exercises and flexibility exercises: Quadriceps, hamstrings, calves, gluteals • TBS/TAS/TLS activities as recommended and tolerated • Single-leg balance/proprioception training with perturbations • CKC concentric and eccentric hamstring and quadriceps PREs at 6 wk • Wk 7: Four-way standing SLR with Thera-Band • Brisk walking/elliptical/bicycle with resistance/StairMaster at 7 wk • Controlled lateral movements at 8 wk • OKC quadriceps strengthening 8 wk • Return to jogging/running progression at 10 wk	• Functional hinged brace for HEP/return to sport for 12–18 mo postoperatively • Flexibility exercises • Plyometrics on leg press at 10 wk • Body weight plyometrics at 12 wk • Sport-specific activities at 12 wk • TBS/TAS/TLS activities as recommended and tolerated • Eccentric quadriceps and hamstring strengthening • Isokinetic quadriceps and hamstring strengthening • Hip abductor/adductor PREs • Quadriceps/hamstring PREs • OKC exercises • CKC exercises	• Functional hinged brace for HEP/return to sport for 12–18 mo postoperatively • Flexibility exercises • Total body strengthening, total arm strengthening, and total leg strengthening (TBS/TAS/TLS) activities as recommended and tolerated • Speed/agility/plyometric training • Sport-specific activities • Eccentric quadriceps strengthening • Proprioception/balance training with perturbations • Isokinetic quadriceps/hamstring strengthening • Hip abductor/adductor PREs • Quadriceps/hamstring PREs • OKC exercises • CKC exercises • Completion of return to running progression • Completion of functional testing algorithm • Return to sport: 4–6 mo postoperatively

Other Therapeutic Exercises

- 4 to 5 weeks postoperatively
  - Hamstring isotonics through full knee ROM
  - Quadriceps Isotonics through full knee ROM
  - Hip three-way SLR with ankle weights (avoid adduction): Progress by 1–2 lb/wk
  - Continue progressing upper-extremity (UE) progressive resistive exercises (PREs) and core stability exercises
- 6 weeks postoperatively
  - Progress hip and hamstring PREs
  - Begin eccentric and concentric quadriceps strengthening

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Focus should be on regaining full quadriceps strength and control in this phase. Special attention must be given to surrounding musculature that may have atrophied during NWB phase, including gluteus medius, gluteus maximus, and core muscles.

Sensorimotor Exercises

- 6 weeks postoperatively
  - Progressive single-leg balance exercises with biomechanical ankle platform system (BAPS), wobble board, Dyna Disc, Bosu ball, etc.
  - Grid exercises
- 8 weeks postoperatively
  - LE perturbation training (e.g., single-leg balance on Dyna Disc with bodyblade and ball tosses)

OKC and CKC Exercises

- CKC: Exercises should be performed three times per week at a minimum. To achieve optimal gains of both muscle strength and endurance, dosage should be 3 × 10 repetitions for each exercise unless otherwise noted.
  - 4 to 5 weeks postoperatively
    - Progress single-leg leg press/total gym from 0° to 90° knee flexion
    - Wall sits: 3 × 30- to 60-second holds
    - Bilateral heel raises
    - Carpet rolls or rolling stools for CKC hamstring strengthening
    - Single-leg bridge with march for core stability and hamstring strengthening
  - 6 weeks postoperatively: Begin quadriceps strengthening
    - Forward stepups focusing on pelvis and LE control and alignment
    - Stepdowns: Slowly, focusing on eccentric quadriceps control
    - Single-leg heel raises
    - Minisquats
    - Partial forward lunges to 30°
    - Single-leg Russian deadlift
  - 7 weeks postoperatively
    - Double-leg ball squats
    - Partial forward and backward lunges to 45°

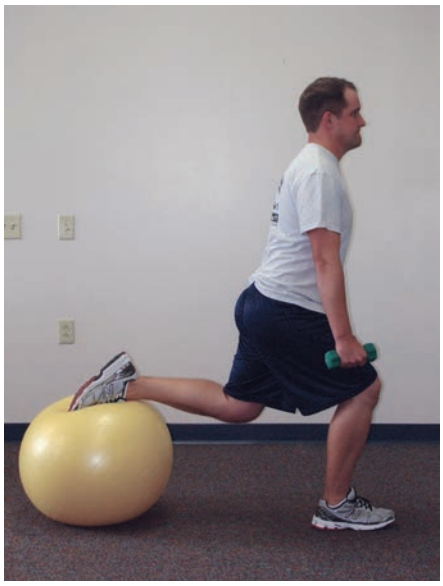

FIGURE 34-20. Lunges on stability ball: Patient performs partial lunge (0° to 45° knee flexion) with back foot propped on stability ball while focusing on keeping hips level and the knee in line with the ankle. This exercise is focused on eccentric quadriceps and gluteus medius strengthening.

    - Lateral stepups
    - Thera-Band sidestepping
  - 8 weeks postoperatively
    - Begin lateral and multiple angle lunges with tibia vertical.
    - Lunges with stability ball (Figure 34-20)
    - Single-leg ball squats
    - Single-leg sit to stand (Figure 34-21)

FIGURE 34-21. Single leg sit to stand to a target: Patient stands 6 to 8 inches away from a sturdy target at approximately thigh height. Patient slowly lowers the hips to the target and back up, focusing on ipsilateral quadriceps and gluteus maximus eccentric and concentric contractions.

- OKC: Exercises should be performed three times per week at a minimum. To achieve optimal gains of both muscle strength and endurance, dosage should be 3 × 10 repetitions for each exercise unless otherwise noted.
  - 5 weeks postoperatively
    - Knee extension 0° to 90° with no weight and against gravity
    - Hamstring curls with resistance
    - Clam exercise with Thera-Band
    - Thera-Band standing three-way SLR (avoid adduction)
  - 7 weeks postoperatively
    - Thera-Band standing three-way SLR (avoid adduction)
  - 8 weeks postoperatively
    - Resisted OKC knee extension

Techniques to Increase Muscle Strength, Power, and Endurance

- Focus should be on single-leg concentric and eccentric quadriceps strengthening, as research has shown that quadriceps muscle power deficits after combined MCL and ACL repair are up to 30.7% compared to the contralateral side at 1 year after surgery.[7]
- Most functional activities use both concentric and eccentric muscle contractions, which makes strengthening both modes a vital part of rehabilitation. Progression of quadriceps strengthening should be fast-paced and should include isokinetic training.
- 6 weeks postoperatively
  - Bicycle exercise with resistance, brisk walking on treadmill
- 8 weeks postoperatively
  - Incline and reverse walking on treadmill, elliptical machine, bicycle with resistance, and StairMaster to enhance cardiovascular fitness.

Neuromuscular Dynamic Stability Exercises

- Progress manual rhythmic stabilization of trunk and core exercises.

Functional Exercises

- 7 weeks postoperatively
  - Begin controlled lateral movements.
  - Sidestepping with Thera-Band
  - Slow and controlled lateral shuffles and carioca

Milestones for Progression to the Next Phase

- Full knee ROM
- Good LE alignment with all single-leg exercises
- Can tolerate 1 to 2 miles of brisk walking without a limp

Phase IV (weeks 8 to 12 postoperatively)

Clinical Pearls

- During this phase, the patient must demonstrate 75% quadriceps strength compared to the contralateral side before starting a return to running program at 10 weeks postoperatively and/or plyometrics, agility, and/or sport-specific exercises at 12 weeks postoperatively.
- It is important that the patient avoid external rotation of the tibia during higher-level activities/exercises to avoid putting stress on the healing graft and/or repair.
- It has become the general consensus that CKC exercises are safer than OKC exercises after knee surgery; however, the trend is toward incorporating OKC knee extension exercises earlier in rehabilitation, as they seem to be more sufficient than CKC exercises for isolated quadriceps strengthening.[7]

Goals

- No knee pain or effusion
- Isokinetic quadriceps strength = 75% of contralateral side
- Functional tests = 75% of contralateral side
- Jogging or running with normal gait pattern
- Good landing mechanics with double- and single-leg plyometrics

Protection

- Discharge brace for activities of daily living at 8 weeks postoperatively, but functional hinged brace for must be used for sport and/or vocation for 12 to 18 months postoperatively.[5,6]

Techniques for Progressive Increase in ROM

- Continue LE stretching/flexibility exercises for quadriceps, hamstrings, calves, and gluteal muscles

Other Therapeutic Exercises

- Continue progressive UE strengthening exercises.
- Continue progressive LE strengthening exercises, including wall squats, lateral lunges, knee extension, vertical squats, stepups, hip abductors/adductors, leg press, and hamstring curls.
- Isokinetic hamstring and quadriceps strengthening.
- Continue progressive core stability exercises.

Sensorimotor Exercises

- Continue progressive balance/proprioception exercises with perturbations, including single-leg BAPS with ball toss and bodyblade, wobble board, and tilt board.

OKC and CKC Exercises

- CKC: Continue progressing as above.
- OKC: Begin OKC knee extension PREs at 8 weeks postoperatively.

Techniques to Increase Muscle Strength, Power, and Endurance

- Continue UE and LE strengthening exercises, avoiding any resisted adduction exercises that put undue stress on graft/repair.
- Focus on eccentric quadriceps and fast-speed isokinetics.

Neuromuscular Dynamic Stability Exercises

- Begin combining UE functional movement with LE control, such as UE medicine ball proprioceptive neuromuscular facilitation patterns with forward, backward, and lateral lunges
- Progress to forward, backward, lateral, and multiple-angle stepdowns with focus on LE control and vertical tibia
- Slide board

Plyometrics

- 10 weeks postoperatively
  - Begin plyometrics on leg press, starting with double leg and progressing to single leg. Focus should be on good LE alignment and soft landing.
  - Initiate slide board exercises (3 × 60 seconds (Figure 34-22)) if patient has good LE control with all other exercises. Make sure patient wears the hinge brace to prevent valgus stress on the knee.
- 12 weeks postoperatively
  - Begin body weight plyometrics and agility exercises when at 75% strength compared to contralateral side, functional hop test at >75% compared to contralateral side, and good control on stepdown.[3] Start with double-leg ladders, box jumps, and vertical jumps, focusing on landing on heels with a flexed knee and good LE control. Patient must be able to jump off and land evenly with both legs and demonstrate good form before progressing to single-leg plyometrics (Figure 34-23).
  - Progress to (1) single-leg lateral jumps when the patient has good control with single leg forward and (2) retro plyometrics.

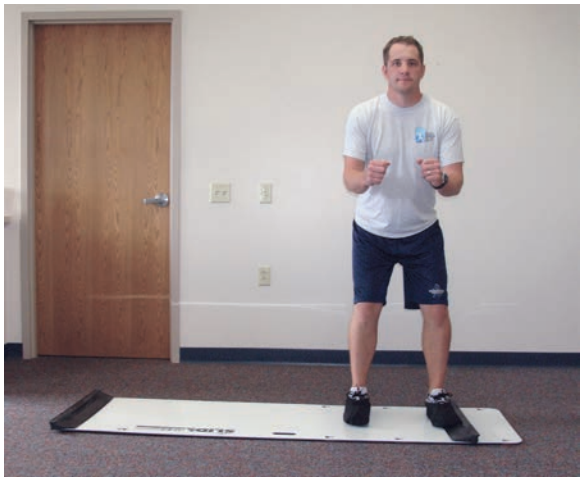

FIGURE 34-22. Slide board side shuffles: Keeping knees bent, toes forward, and hips level, the patient performs side shuffles on a slide board until fatigue.

FIGURE 34-23. Demonstration of proper landing mechanics.

Functional Exercises

- 10 weeks postoperatively
  - Begin jogging and/or running progression when 75% strength compared to contralateral side has been achieved, functional hop test is >70% compared to contralateral side, and good control on stepdown is demonstrated. Progression may start with fast walk, then progress to light jog, run, sprint without resistance, and sprint with bungee cords.
- 12 weeks postoperatively
  - Begin higher-level lateral movements, starting with lateral cutting, figure-eights, and zigzags and progressing to lateral shuttle with bungee cord and combination movements such as plant, cut, and pivot.

Sport-Specific Exercises

- 12 weeks postoperatively
  - At 12 weeks postoperatively, begin skilled, sport-specific exercises if 75% quadriceps strength and 75% functional hop test compared to contralateral side have been achieved.

Milestones for Progression to the Next Phase

- 75% isokinetic quadriceps strength compared to contralateral side

- 75% single-leg hop distance compared to contralateral side
- Able to jog or run without limp
- Good kinematic control with double-leg and single-leg jumps

Phase V (weeks 12 to 24 postoperatively)

Clinical Pearls

- It is important that athletes do not return to sport before they are physically ready, as the rate of reinjury is high in patients with ligament injuries of the knee.
- Davies and Zillmer developed a functional testing algorithm that focuses on fundamental and progressive stages of rehabilitation for athletes planning to return to sport.[8] The athlete must complete all stages of the functional tests before full participation in sports. Successful return to sport usually occurs at 4 to 5 months postoperatively with use of a functional hinged brace for 12 to 18 months postoperatively.

Goals

- Negative valgus stress test of the knee at both 0° and 30° knee flexion
- Demonstration of good landing mechanics with double- and single-leg plyometrics
- Completion of running progression program[2]
- Completion of sport-specific activities/functional exercise program/functional testing algorithm[6]
- Functional tests
  - At the end of this phase, if planning to return to sport, the athlete should complete the functional testing algorithm presented by Davies and Zillmer.[8]
    - Subjective: Pain score <3 on a visual analogue scale
    - Basic measurements: <10% bilateral comparison
    - KT1000 ligament arthrometer testing: <3 mm bilateral comparison
    - Balance test: <30% bilateral comparison
    - CKC supine isokinetic test: <30% bilateral comparison
    - OKC isokinetic test: <25% bilateral comparison
    - CKC squat isokinetic test: <20% bilateral comparison
    - Functional jump test: <20% bilateral comparison
    - Functional hop test: <15% bilateral comparison
    - LE functional test: <90 seconds for males, <120 seconds for females
    - Sport-specific test: <10% bilateral comparison
- Continue UE and LE strengthening program, proprioception training, endurance exercises, plyometric training, and sport-specific exercises throughout this phase.
- Emphasis should remain on speed/agility program, functional exercise drills, eccentric quadriceps strengthening, and fast-speed isokinetics of hamstring and quadriceps muscles.
- Completion of a full running progression program, such as the program presented by Phisitkul et al., in one session[2]
  - Jog 1 mile.
  - Five successive 100-yd sprints at half-speed
  - Five successive 100-yd sprints at three-fourths speed
  - Five successive 100-yd sprints at full speed
  - Five zigzag sprints at half speed
  - Five zigzag springs at full speed

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Continue strengthening the dynamic stabilizers of the medial side of the knee, including the semimembranosus complex, quadriceps, and pes anserine tendons.
- Continue quadriceps and hamstring fast-speed isokinetic strengthening.
- Continue flexibility exercises.
- Continue proprioception/balance exercises

Exercises and Other Techniques for Prevention of Recurrent Injury

- Continue use of hinged brace for 12 to 18 months postoperatively for all athletic activity.
- Continue high-level plyometric training with focus on proper landing mechanics.
- Continue speed and agility training. Focus on good LE alignment during lateral cutting, lateral shuffles, and jumping activities to valgus stress to knee joint and tension on the MCL.

Evidence

Chen L, Kim PD, Ahmad CS, et al: Medial collateral ligament injuries of the knee: current treatment concepts. *Curr Rev Musculoskelet Med* 1:108–113, 2008.

A review of the current treatment concepts of the medial collateral ligament of the knee. (Level V evidence)

Davies GJ, Zillmer D: Functional progression of exercise during rehabilitation. In Ellenbecker T, editor: *Knee Ligament Rehabilitation*, New York, 2000, Churchill-Livingstone, pp 345–360.

The functional testing algorithm presented in this article serves as a guideline for clinicians to determine when an athlete is ready to return to sport after injury. (Level IV evidence)

Halinen J, Lindahl J, Hirvensalo E: Range of motion and quadriceps muscle power after early surgical treatment of acute combined anterior cruciate and grade-III medial collateral

ligament injuries: a prospective randomized study. *J Bone Joint Surg Am* 91:1305–1312, 2009.

A comparison of repair or nonoperative treatment of the MCL on ROM and quadriceps muscle strength in patients with combined MCL and ACL injuries. Results showed decreased ROM with operative treatment at 6-, 12-, and 36-week follow-up examinations, but no difference at 52 weeks and a 30.7% quadriceps muscle power deficit with MCL repair compared to 20.5% quadriceps muscle power deficit with nonoperative treatment. These results highlight the importance of early ROM and quadriceps strengthening postoperative MCL repair. (Level I evidence)

Indelicato PA: Non-operative treatment of complete tears of the medial collateral ligament of the knee. *J Bone Joint Surg Am* 65:323–329, 1983.

A prospective study comparing results of operative and non-operative management of complete, Grade III, isolated MCL tears. The results support no obvious advantage of surgical repair and highlights importance of early-protected mobilization of the knee in a cast or brace. (Level IV evidence)

Kovachevich R, Shah JP, Arens AM, et al: Operative management of the medial collateral ligament in the multi-ligament injured knee: an evidence-based systematic review. *Knee Surg Sports Traumatol Arthrosc* 17:823–829, 2009.

This review suggests that surgical repair or reconstruction of the MCL in the multi-ligament-injured knee yields satisfactory results. (Level III)

Phisitkul P, James SL, Wolf BR, et al: MCL injuries of the knee: current concepts review. *Iowa Orthop J* 26:77–90, 2006.

This review supports conservative management of most MCL injuries and offers a goal-oriented rehabilitation program based on recent clinical studies. The review also includes incidences when surgery may be warranted and summarizes basic surgical technique and postoperative rehabilitation. (Level V evidence)

Rice DA, McNair PJ: Quadriceps arthrogenic muscle inhibition: neural mechanisms and treatment perspectives. *Semin Arthritis Rheum* 40:250–266, 2010.

Supports the use of cryotherapy, TENS, and NMES to decrease pain and swelling and decrease quadriceps muscle inhibition after knee surgery. (Level V evidence)

Romeyn RL, Jennings J, Davies GJ: Surgical treatment and rehabilitation of combined complex ligament injuries. *N Am J Sports Phys Ther* 3:212–225, 2008.

A review of the current literature of the optimal surgical procedures and rehabilitation protocol for patients with combined/complex ligament injuries of the knee. The article supports the selection of selected OKC and CKC exercises and the milestones for progression through each phase of rehabilitation and return to activity/sport. (Level V evidence)

Wijdicks CA, Griffith CJ, Johansen S, et al: Injuries to the medial collateral ligament and associated medial structures of the knee. *J Bone Joint Surg Am* 92:1266–1280, 2010.

This comprehensive literature review summarizes the most favorable nonoperative and operative treatment options for injuries of the medial structures of the knee. There is a consensus that nonoperative treatment of Grade III MCL tears produces more favorable outcomes. The review describes incidences when surgery may be warranted. (Level IV evidence)

Wilson TC, Satterfield WH, Johnson DL: Medial collateral ligament "tibial" injuries: indication for acute repair. *Orthopedics* 27:389–393, 2004.

These authors claim that the current research suggests Grade III and some Grade II MCL injuries with tibial insertion avulsions lead to chronic knee instability and worse outcomes and that surgical repair is therefore the best intervention. Two case studies of athletes undergoing early surgical repair and the same postoperative rehabilitation protocol led to good outcomes and return to sport-specific activities in a hinged brace at 3 months and return to full sports at 4 months postoperatively. (Level IV evidence)

Multiple-Choice Questions

QUESTION 1. In cases of isolated MCL tears, surgery usually is not warranted unless:

A. The patient demonstrates valgus laxity greater than 10 mm at both 0° and 30° of knee flexion.
B. The posterior oblique ligament is torn in conjunction with the superficial and deep medial collateral ligaments.
C. The patient is an elite athlete who needs to perform high-powered lateral cutting for their sport.
D. The patient demonstrates anteromedial instability of the knee.

QUESTION 2. After repair of an acute isolated MCL tear, the patient may progress to FWB in a hinged brace at the end which week?

A. 1
B. 2
C. 3
D. 4

QUESTION 3. Early knee ROM in a hinged brace after MCL repair/reconstruction is necessary to prevent adhesion formation during early postoperative rehabilitation, but should be limited to _____ for the first 3 weeks.

A. 0° to 30°
B. 30° to 60°
C. 30° to 90°
D. 60° to 90°

QUESTION 4. At 5 weeks after isolated MCL repair/reconstruction, patients may discharge use of crutches if they have:

A. Full knee ROM
B. Good quadriceps control
C. No valgus laxity at both 0° and 30° knee flexion
D. No knee pain or effusion

QUESTION 5. The patient must demonstrate _____ before returning to sport after isolated MCL repair/reconstruction.

A. 90% isokinetic quadriceps strength compared to the contralateral side
B. Ability to run with a normal gait pattern
C. 60% hamstring/quadriceps ratio with isokinetic strength testing at 60°/sec
D. Single-leg plyometrics with no knee valgus

Answer Key

QUESTION 1. Correct answer: **D** (see Surgical Indications)

QUESTION 2. Correct answer: **C** (see Phase II: Postoperative Rehabilitation)

QUESTION 3. Correct answer: **C** (see Immediate Postoperative Rehabilitation)

QUESTION 4. Correct answer: **B** (see Phase II: Rehabilitation)

QUESTION 5. Correct answer: **A** (see Phase III: Rehabilitation)

BEYOND BASIC REHABILITATION: RETURN TO FOOTBALL AFTER MEDIAL COLLATERAL LIGAMENT SURGERY

Luke O'Brien, BPhty, GCertPhty, SCS, Nicholas Kennedy, BS, and Robert F. LaPrade, MD, PhD

Introduction

ASPECTS OF FOOTBALL THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- There are a number of physical performance characteristics that are essential to a successful return to football. These include throwing, running, cutting, accelerating, decelerating, catching, blocking, jumping, and tackling.
- The degree to which each of these characteristics is emphasized in a rehabilitation program is position-dependent, with appropriate adjustments made to emphasize position-specific demands.
- Restoration of knee stability and full knee range of motion (ROM) are fundamental to the ability to return to play.
- Position-specific energy system and muscular strength characteristics should be identified and developed in the rehabilitation program.

- Isolated anterior cruciate ligament (ACL) injuries are extremely common for National Football League (NFL) athletes. Shah et al. reported 209 ACL injuries over a 5-year span (1994–1998).[1]
- High occurrence of previous ACL injuries in players at NFL combine.[2]
- Football accounts for the highest percentage of ACL, medial collateral ligament (MCL) multiligamentous injuries, with 31% to 37% of the injuries seen clinically being the result of football.[3,4]
- Return to play following ACL reconstruction has been reported to be 63%. This is lower than common perceptions.[1]

Literature

- To the knowledge of the authors of this chapter, there is no literature regarding return to play at the NFL level after a combined ACL, MCL multiligamentous injury and subsequent surgical reconstruction.
- With regard to return to play from isolated ACL injuries, the injury has been shown to decrease game

performance of NFL players and has been reported to inhibit up to 37% of players who experience said injury from returning to play.[1,5]
- Grade III MCL injuries have been reported to heal well with conservative and with surgical treatment.[6-10]

Advanced Rehabilitation Program

- The authors felt that an additional phase—phase 0—should be added to the rehabilitation protocol for this injury. Phase 0 focuses on mobility and base strength following surgery and creates the foundation upon which the physiological benefits of the advanced rehabilitation exercises are built.
- The weekly structure of the rehabilitation program commonly involves 6 or 7 days per week of targeted exercise. Recovery, particularly in the strengthening phases, plays an important role in the athlete's ability to complete the prescribed sessions.
- To assist post exercise recovery, we advocate cold water immersion in 59°F (15°C) water for 15 minutes. These parameters have been shown to improve subsequent exercise performance by 10% compared to active recovery, contrast water therapy, and hot-water immersion, and they have also been found to reduce muscle soreness.[11,12]
- In the absence of an available immersion pool, a cryotherapy device such as a Game Ready cold compression device may be a viable alternative. Although no results on it's exercise performance efficacy have been published, it has been shown to reduce postsurgical pain and inflammation[13]
- Quality sleep is an important recovery element. Athletes are encouraged to set room temperature to between 66°F and 70°F, maintain a regular sleep–wake cycle, and avoid naps of long duration that may interfere with nighttime sleep.
- Although used extensively outside the United States, global positioning system (GPS) monitoring systems (such as Catapult) have only recently begun to catch on in sporting environments. GPS systems, when interpreted correctly, can provide valuable training information that can be used to effectively manipulate training variables to minimize the risk of unnecessary training volume spikes and to decrease reinjury risk.

Phase 0: Mobility and Base Strength

Periodization

- Linear periodization is focused on restoring correct muscle-firing patterns and patellofemoral and tibiofemoral joint mobility.
- Macrocycles are used throughout the rehabilitation protocol and are focused upon restoration of performance and return to play.
- Mesocycles are implemented during the first 3 months of the rehabilitation process and are focused upon restoration of normal joint ROM, muscle initiation patterns, and endurance base building.

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Flexibility/joint mobility for joint stability
- Training with optimum posture
- Sensorimotor and balance training
- Core training
- Cardiorespiratory training
- Training for optimum muscle balance
- Training for optimum muscular endurance

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload
- Principle of variation
- Principle of individualization
- Principles of specificity–specific adaptation to imposed demands (SAID)

Application of Acute Training Variables

- To properly design the athlete's rehabilitation program, a thorough needs analysis is completed. This includes position-specific athletic performance needs, prior injury history, physical strengths and weaknesses, and major team date milestones such as start of training camp, start of preseason, and start of regular season.
- The established time milestones can then be matched with the anticipated rehabilitation phases. Because the timeline of recovering from surgery rarely perfectly match the start of training camp or the start of the regular season, the length of each rehabilitation phase may need to be manipulated (either lengthened or shortened), based upon the athlete's recovery and performance needs.
- The authors advocate a backward-planning approach when determining the length of each rehabilitation phase. In this approach, high-impact activities are initiated as late in the recovery as possible while still allowing sufficient time for the athlete to fully develop the training characteristic. For example, if the return-to-play date is 10 months in the future, there is limited value in initiating a running progression program at 5 months. Rather, delaying running until 7 months allows for a continued focus on muscular development, accommodation of the joint to increasing loads, and restoration of joint homeostasis while still allowing sufficient time for running development.
- The goal of this phase is to regain mobility, prevent joint stiffness, and limit scar tissue formation while protecting the reconstructed ligaments.[14]
- ROM is restored through a combination of exercise and manual therapy.
- Patellar mobilization (Figure 34-24*A,B*) is used to restore patellofemoral mobility, help to ensure the integrity of the anterior fat pad interval and suprapatellar pouch, and prevent a decrease in joint mobility.[15,16,18,19]

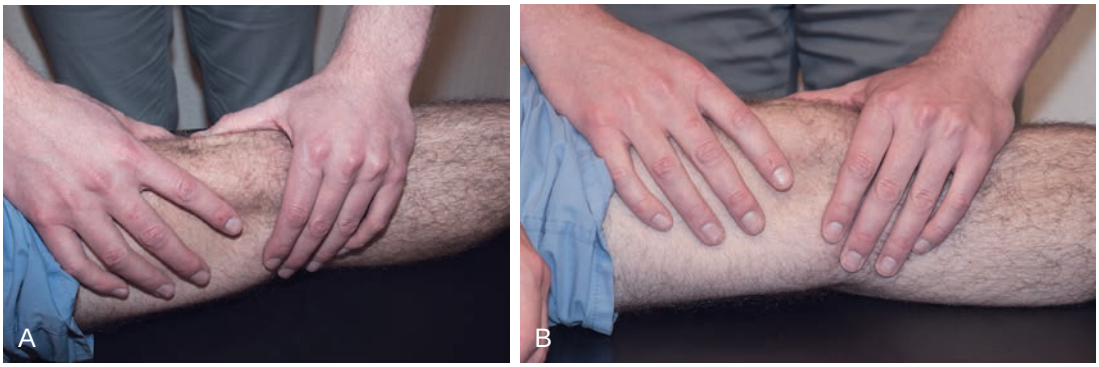

FIGURE 34-24. Patellar mobilization.

- With extension mobilization, the aim is to restore symmetrical extension, allowing the quadriceps to function in their inner range while also allowing joint contact forces to be distributed over the entire available surface area.[20]
- Wall slides and flexion on a Swiss ball help to restore flexion ROM.
- Quadriceps exercises are first focused on restoring the correct initiation pattern. This involves high-repetition, low-intensity parameters. Because of the low intensity, minimal rest is required between sets.
- Once the correct muscle patterning is established, the exercise parameters are adjusted to stress type 1 slow-twitch fibers, which atrophy predominantly following surgery. These exercises have an increasing intensity of at least 25 repetitions and a 45-second to 1-minute rest period.
- Training frequency for both ROM and muscle initiation exercises should be numerous: two to four times per day, 7 days per week.
- Sample exercise and training parameters are outlined in Table 34-1.

Phase I: Advanced Strength and Conditioning Programs

Periodization

- Linear periodization: Focused on restoring correct muscle pattern initiation and building a muscular endurance base
- Undulating
- Macrocycles are used throughout the rehabilitation protocol and are focused upon restoration of performance and return to play.
- Mesocycles implemented during the first 3 months of the rehabilitation process are focused upon restoration of normal joint ROM, muscle initiation patterns, and endurance base building.

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Flexibility/joint mobility for joint stability
- Training with optimum posture
- Sensorimotor and balance training
- Core training
- Cardiorespiratory training
- Training for optimum muscle balance
- Neuromuscular dynamic stability exercises
- Functional training
- Sport-specific training
- Training for optimum muscular endurance

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload
- Principle of variation
- Principle of individualization

Table 34-1 Range of Motion and Muscle Initiation (weeks 1–6)

	Repetitions	Sets	Frequency
Wall slides	10 min	1	2–4 times daily, 5–7 times per week
Patella mobility (image 1 and image 2)	10 min	1	2–4 times daily, 5–7 times per week
Extension mobilization	5 min	1	2–4 times daily, 5–7 times per week
Flexion on Swiss ball	10 min	1	2–4 times daily, 5–7 times per week
Quadriceps initiation continuum: • Patellar glide • Patellar glide with biofeedback: holds • Patellar glide with TKE • TKE with manual overpressure • Straight-leg raise • Standing TKE with sports cord	25+	3	2–4 times daily, 5–7 times per week

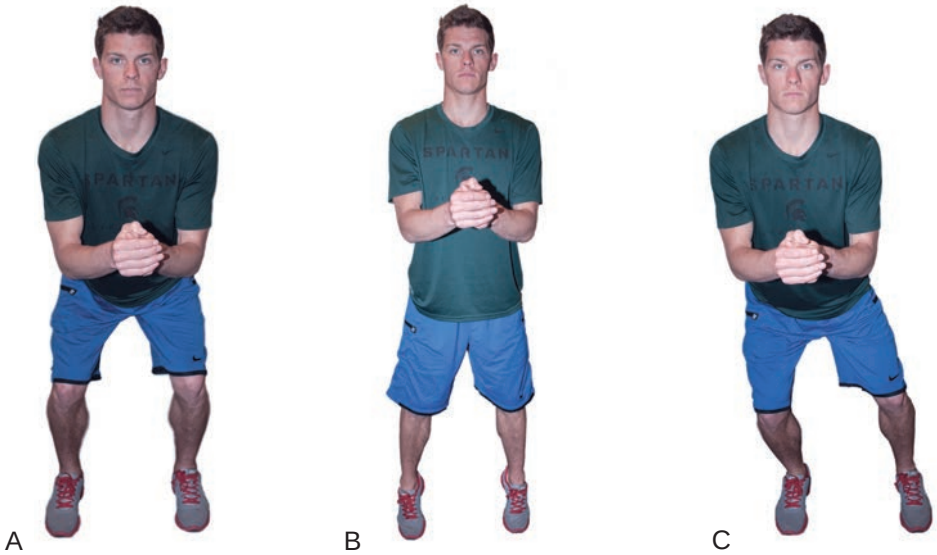

FIGURE 34-25. Squat progression.

- Principles of specificity–specific adaptation to imposed demands (SAID)

Application of Acute Training Variables

- Exercise parameters are designed to establish a muscular endurance base upon which further gains in strength and power can be made in later phases.
- Set and repetition structure is generally 3–6 × 20+ to promote the development of a muscular endurance base (reference). Three sets are commonly prescribed at the beginning of the program, with an increase in set number serving to incrementally increase training volume over time.
- Rest intervals between sets are 30–45 seconds
- Training frequency is usually three times per week. Strength days are alternated with low load/active recovery days, with 1 day of the week completely off.
- Training duration is between 60 and 90 minutes, including active warmup, strength session, cool down, and ice time.
- Training volume is manipulated depending upon intensity. Generally, during this stage of rehabilitation, intensity remains constant while overload is created through increased training volume (e.g., from three sets to six sets).
- Exercises at this stage of recovery focus on double-leg, shallow range motions (squat progression; Figure 34-25*A*, *B*, and *C*) and tuck squat (Figure 34-26*A*,*B*) or single-leg static holding positions (static box hold with medicine ball press) (Figure 34-27*A*,*B*).
- This emphasis allows the athlete to gain muscular control over simpler movement patterns before progressing to more challenging movements.

TIMELINE 34-4: **Return to Football after Medial Collateral Ligament Surgery**

PHASE 0 (weeks 1 to 6 postoperatively)

Weeks 1 to 2

- Immobilizer brace
- ROM 0°–90°: Wall slides, flexion on Swiss ball, end of table
- Non–weightbearing
- Patellofemoral mobilization
- Extension mobilization
- Quadriceps initiation drills
- Ankle dorsiflexion stretch
- Ankle pumps
- Ice

Weeks 3 to 6

- Immobilizer brace
- Full passive ROM: Wall slides, flexion on Swiss ball, end of table
- Non–weightbearing
- Patellofemoral mobilization
- Extension mobilization
- Quadriceps continuum
- Ankle dorsiflexion strength
- Ankle pumps
- Ice

PHASE I (weeks 7 to 12 postoperatively)

- Hinged knee brace
- Wk 6–8: Wean off crutches
- Flexion/extension/patellofemoral mobilization as needed
- Stationary bike
- Incline treadmill walking
- Pool
- CKC exercises: Endurance base building focus
- Shallow range double-leg or static single-leg CKC exercises
- Begin core + UE lifting + cardio
- Ice

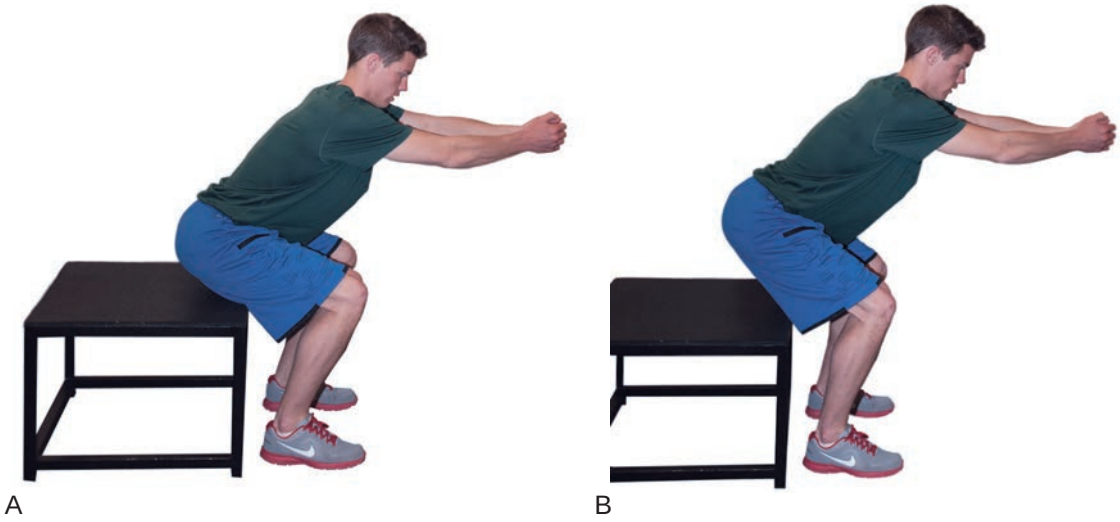

FIGURE 34-26. Tuck squat.

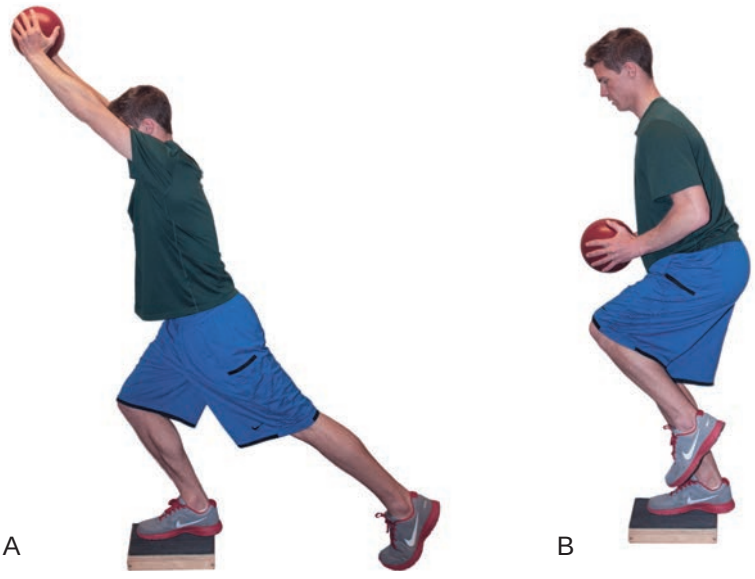

FIGURE 34-27. Single-leg static holding position: static box hold with medicine ball press.

TIMELINE 34-4: **Return to Football after Medial Collateral Ligament Surgery** (Continued)

PHASE II (weeks 13 to 24 postoperatively)

Weeks 13 to 18

- Flexion/extension/patellofemoral mobilization as needed
- Stationary bike
- Incline treadmill walking
- Pool
- CKC exercises: Muscular strength focus
- OCK exercises: Hamstring and gluteals
- Single-leg through range CKC exercises
- Core + UE lifting + cardio

Weeks 19 to 24

- Stationary bicycle
- Pool
- Alter G running progression
- CKC exercises: Muscular power focus
- OCK exercises: Hamstring and gluteals
- Core + UE lifting + cardio

PHASE III (weeks 25 to 29+ postoperatively)

Weeks 25 to 28

- Stationary bicycle
- Pool
- Vail Sports Test + girth measurements
- Land-based running progression
- CKC exercises: Olympic lifting incorporated
- Core + UE lifting

Weeks 29+

- Stationary bicycle
- Pool
- Week 29: Single-plane agility
- Wk 30–32: Multiplanar agility
- CKC strength maintenance plan
- Agility T-Test
- Resume training

Table 34-2 Muscular Endurance Base Building (weeks 7–12)

	Repetitions	Sets	Rest	Intensity	Frequency
Double-leg press	20+	3–6	1–2 min	50% 1RM	3–4 times/wk
Squat progression (Figure 34-25) • Body weight squat • Body weight squat to calf raise • Body weight squat to weightshift	30 (10 each)	3–6	1–2 min	50% 1RM	3–4 times/wk
Static box hold with medicine ball press (Figure 34-27)	20+	3–6	1–2 min	50% 1RM	3–4 times/wk
Single-leg deadlift	1+ min	3–6	1–2 min	50% 1RM	3–4 times/wk
Double-leg bridges with alternating leg lift	20+	3–6	1–2 min	50% 1RM	3–4 times/wk
Tuck squat (Figure 34-26)	1+ min	3–6	1–2 min	50% 1RM	3–4 times/wk
Static hold with two-way slider disc	20+	3–6	1–2 min	50% 1RM	3–4 times/wk

- Sample exercises and training parameters are outlined in Table 34-2.

Phase II: Performance Enhancement Training Techniques

Periodization

- Linear periodization with a focus on gaining strength and power upon the muscular endurance foundation that has been built.
- Undulating
- Macrocycles are used throughout the rehabilitation protocol and are focused upon restoration of performance and return to play.
- Mesocycles are implemented during the second 3 months and are focused more on improving strength and power.
- Microcycles

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Flexibility/joint mobility for joint stability
- Training with optimum posture
- Sensorimotor and balance training
- Core training
- Cardiorespiratory training
- Training for optimum muscle balance
- Training for optimum muscle functional strength
- Training for optimum muscle functional power
- Neuromuscular dynamic stability exercises
- Functional training
- Sport-specific training

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload
- Principle of variation
- Principle of individualization
- Principles of SAID

Application of Acute Training Variables

- During this performance enhancement phase, a liner periodization approach is used to first develop muscular strength and then muscular power.
- A 6-week period is dedicated to the development of each physiological characteristic.

Muscular Strength (weeks 12 to 18)

- Sets and repetitions are generally 3–6 × 8–12 to promote the development of muscular strength. This structure allows the clinician some leeway to alter training intensity from session to session. For example, a higher-intensity session may have a 3 × 8 structure, while a lower intensity session may be 4–5 × 12.[21]
- The rest interval between sets increases from the endurance phase. Here, 1 or 2 minutes is available for the athlete to recover before further sets are conducted.
- Intensity is increased to 70% to 85% of 1RM. For many exercises, this is difficult to accurately calculate; therefore, an approach where appropriate load is added to an exercise so that the athlete can complete the prescribed repetitions without loss of form or control is advocated.
- A training frequency of 2 days on followed by 1 active recovery/low-impact day can be used in this phase. This allows for 4 training days, 2 active recovery days, and 1 day off.
- Training duration is typically between 60 and 90 minutes, including active warmup, strength session, cool-down, and ice time.
- Training volume can be manipulated by altering the set and repetition structure. Generally, lower-intensity sessions (higher repetitions) predominate in the first 3 weeks.
- Some specific exercises used in the training include a single-leg squat with sport cord resistance (Figure 34-28*A,B*) and a balance squat (Figure 34-29*A,B*). Although there are many exercises that are suitable at this stage of recovery, the authors advocate the use of single-leg exercises that may initially be completed with a shallow ROM and are steadily increased as strength and proof of control allow.

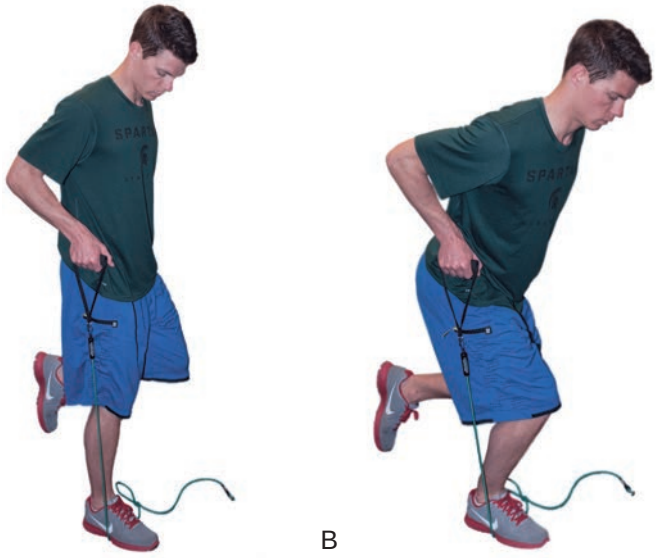

FIGURE 34-28. Single-leg squat with sport cord resistance.

- Leg extension, forward and walking lunges are avoided. The authors feel that these exercises place significant and unnecessary stress on the anterior knee, increasing the risk for the development of anterior knee pain and delaying the total recovery time.
- Sample exercises and training parameters are outlined in Table 34-3.

Muscular Power (weeks 18 to 24)

- A set and repetition structure of 1 to 3 × 1 to 6 is used to develop muscular power. As with strength, the number of sets and repetitions can be manipulated to vary training intensity between sessions, with lower repetitions equating to increased training intensity.
- The increased intensity necessitates an increase in rest time between sets. During muscular power development, 3 to 5 minutes between sets is allowed for recovery.
- Because speed of contraction is emphasized in this phase, the loads used during exercise are decreased from the strength phase to 30% to 45% of 1 RM. Practically, the athlete should be able to complete each exercise set without failure of form or intensity due to the prescribed load.
- Training frequency remains constant at 2 days on, followed by an active recovery/low-impact day. One day in the week is committed to being completely off.
- A typical training duration at this stage is 45 to 60 minutes. The higher intensity dictates a shorter training time.
- As with the strengthening phase, volume is constantly manipulated through adjustments in the set + repetition structure. Commonly, volume is added to the

FIGURE 34-29. Balance squat.

Table 34-3 Muscular Strength Development (weeks 13–18)

	Reps	Sets	Rest	Intensity	Frequency
Single-leg press	8–12	3–6	1–2 min	70%–85% of 1RM	3–4 times/wk
Single-leg squat with sport cord (Figure 34-28)	8–12	3–6	1–2 min	70%–85% of 1RM	3–4 times/wk
Balance squat (Figure 34-29)	8–12	3–6	1–2 min	70%–85% of 1RM	3–4 times/wk
Single-leg deadlift with kettle bell	8–12	3–6	1–2 min	70%–85% of 1RM	3–4 times/wk
High bench stepups with dumbbells	8–12	3–6	1–2 min	70%–85% of 1RM	3–4 times/wk
Reverse lunge	8–12	3–6	1–2 min	70%–85% of 1RM	3–4 times/wk

program over time by adding sets while repetitions and intensity remain constant.

- Specific exercises prescribed in this phase include reverse lunge into hip drive (Figure 34-30*A*,*B*) and prone leg press on shuttle with arm drive (Figure 34-31*A*,*B*).
- Exercise prescription focuses on power movements with the foot remaining on the ground. It is the authors' opinion that this allows for the safest training environment while providing adequate stimulus for muscular power development. Position players for whom jumping is a component of their game will require that ballistic movements with the foot leaving the ground be built into the plan. This can be done after 2 to 3 weeks with appropriate instruction on landing technique and strategies.
- Sample exercises and training parameters are outlined in Table 34-4.

Phase III: Sport-Specific Training

Periodization

- Linear periodization with a focus on speed, quickness, agility, and sport- and position-specific exercises to return to play
- Undulating
- Macrocycles are used throughout the rehabilitation protocol and are focused upon restoration of performance and return to play.

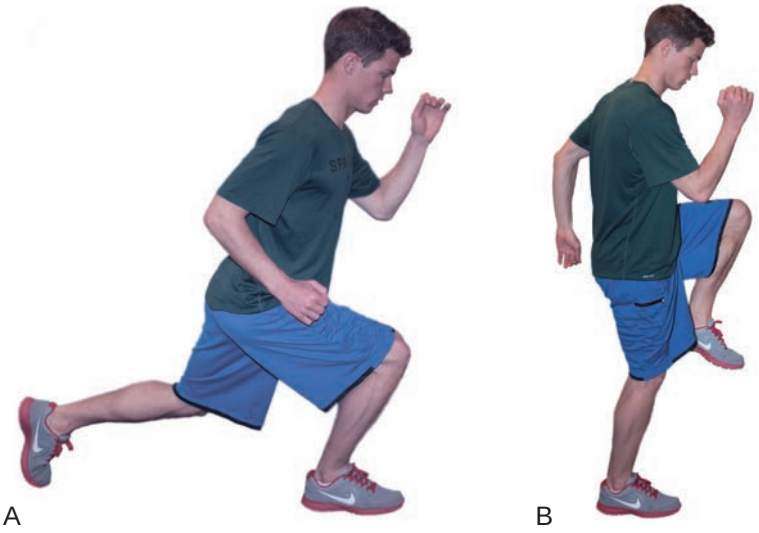

FIGURE 34-30. Reverse lunge into hip drive.

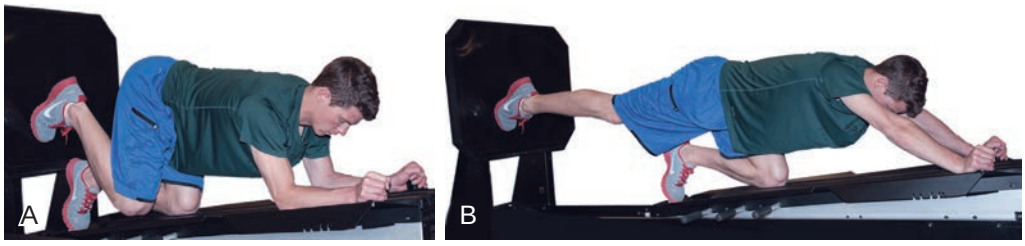

FIGURE 34-31. Prone leg press on shuttle with arm drive.

Table 34-4 Muscular Power Development (weeks 19–24)

	Repetitions	Sets	Rest	Intensity	Frequency
Single-leg press	1–6	1–3	3–5 min	30%–45% of 1RM	1–3 times per week
Reverse lunge into hip drive (Figure 34-30)	1–6	1–3	3–5 min	30%–45% of 1RM	1–3 times/wk
Prone press on shuttle with arm drive (Figure 34-31)	1–6	1–3	3–5 min	30%–45% of 1RM	1–3 times/wk
Lateral agility with sports cord	1–6	1–3	3–5 min	30%–45% of 1RM	1–3 times/wk
Lateral stepping with sports cord resistance	1–6	1–3	3–5 min	30%–45% of 1RM	1–3 times/wk
Forward drive with sports cord resistance	1–6	1–3	3–5 min	30%–45% of 1RM	1–3 times/wk

- Mesocycles for the last phase of rehabilitation are focused on sport- and position-specific exercises as well as regaining speed and quickness so the athlete can return to play.

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Flexibility/joint mobility for joint stability
- Training with optimum posture
- Sensorimotor and balance training
- Core training
- Cardiorespiratory training
- Multiplanar training activities
- Training for optimum muscle balance
- Training for optimum muscle functional strength
- Training for optimum muscle functional power
- Neuromuscular dynamic stability exercises
- Training for speed, agility, quickness (SAQ)
- Plyometric training
- Functional training
- Sport-specific training
- Conditioning training

Olympic Lifts Used in the Training Program

- Snatch
- Clean and jerk
- Power clean

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload
- Principle of variation
- Principle of individualization
- Principles of SAID

Application of Acute Training Variables

- Similar to the prior phase, the sport-specific training phase is divided into two 4-week periods. The first 4-week period is characterized by the incorporation of powerlifting moves and the initiation of a running progression. The second 4-week phase is dedicated to the development of the position-dependent speed and agility movements required to return the athlete to play.
- Powerlifts and running progression
  - Powerlifts are introduced to the program at this time and include hang clean, power clean, and jump shrugs. They utilize the same acute training variables as the power exercises in the prior phase. They are not completed in isolation, but rather incorporated as key components in a wider-ranging power program that includes exercises from the prior phase.
  - Sample exercises and training parameters are listed in Table 34-5.
  - A running progression is initiated in this phase. It is a walk-run program that incrementally increases running volume over a 5-week period.
  - The volume of running can be tailored to the athlete's playing position. A lineman requires less total running time than a running back. Therefore, a lineman may stop the running progression at a 2-minute run: For example, a 3-minute walk × 4, whereas a running back may complete the running progression of 20 minutes of constant running.
  - Sample running progression is outlined in Table 34-6.
- Speed + agility
  - With the successful completion of a running progression, the athlete can begin a speed and agility program.

Table 34-5 Power Lifts during Running Progression (weeks 24–28)

	Repetitions	Sets	Rest	Intensity	Tempo	Frequency
Hang clean	1–6	1–3	3–5 min	30%–45% of 1RM	Explosive	1–3 times/wk
Power clean	1–6	1–3	3–5 min	30%–45% of 1RM	Explosive	1–3 times/wk
Jump shrugs	1–6	1–3	3–5 min	30%–45% of 1RM	Explosive	1–3 times/wk

Table 34-6 Running Progressions: Position-Dependent (Skill Positions) (weeks 24–28)

Running Progression (weeks)	Run Time (min)	Walk Time (min)	Frequency
1	1	4	3 times/wk
2	2	3	3 times/wk
3	3	2	3 times/wk
4	4	1	3 times/wk
5	20	–	3 times/wk

- The first week of the program focuses on single-plane agility. Multiplanar movements and a focus on increasing speed occur in the following weeks.
- A typical agility program involves completion of three sets of four different drills. Each drill will have a specific component (first step speed, deceleration, foot placement) that is emphasized and developed.
- A 3- to 5-minute rest interval is used to allow for complete recovery between sets. A heart rate monitor can be a useful tool to determine recovery time. After an agility set, heart rate can be monitored, and, once it has returned to resting levels, the next set can start.
- Initial agility drills, which focus on technique and skill acquisition, are typically completed at lower intensity levels. As the skills are learned, the intensity level progressively increases until the athlete is training at 100% effort.
- Three agility sessions are usually completed per week, with sessions lasting between 30 and 60 minutes depending upon recovery time. Training volume is increased by manipulating training intensity to create overload.
- Some of the exercises used during the single-plane agility work include dip-and-touch and a weave run. Once the program has advanced to multidirectional agility, drills such as sprint, shuffle touch, and jump over–sprint are useful in allowing the athlete to develop the performance characteristics necessary to return to football.
- Sample exercises and training parameters are outlined in Table 34-7.

Sports Performance Testing

General Information

- General history
- Subjective questionnaires
- Medical history
- Sports injury history
- Surgical history
- Chronic conditions/medication

Specific Tests

Clearance to Begin Running Progression: Beginning of Phase III

- Thigh girth 10 cm proximal to the superior border of the patella
- The Vail Sports Test[22]: The Vail Sports Test is a four-test battery of exercises that assesses an athlete's muscular endurance, muscular power, and ability to accept eccentric load.
- An athlete must demonstrate thigh girth within 1 cm of unaffected side and pass the Vail Sports Test to commence the running progression.

Table 34-7 Speed and Agility (weeks 29–32)

	Week of Agility Progressions	Intensity	Rest	Frequency	Sets
Weave run	1	50%	3–5 min	3 times/wk	3
Zigzag shuffle	1	50%	3–5 min	3 times/wk	3
Dip and touch	1	50%	3–5 min	3 times/wk	3
Circle around	1	50%	3–5 min	3 times/wk	3
Jump over–sprint	2	75%	3–5 min	3 times/wk	3
Front–back shuffle	2	75%	3–5 min	3 times/wk	3
Sprint–shuffle	2	75%	3–5 min	3 times/wk	3
Figure-6s	2	75%	3–5 min	3 times/wk	3
Up 2, back 1	3	100%	3–5 min	3 times/wk	3
Shuffle, explode, touch	3	100%	3–5 min	3 times/wk	3
Sprint, shuffle, touch	3	100%	3–5 min	3 times/wk	3
Run-through with hand plants	3	100%	3–5 min	3 times/wk	3
Run-through	4	100%	3–5 min	3 times/wk	3
Shuffle-through	4	100%	3–5 min	3 times/wk	3
Sprint–backpedal	4	100%	3–5 min	3 times/wk	3
Up and around	4	100%	3–5 min	3 times/wk	3

Clearance to Resume Training: Completion of Speed and Agility

- An agility T test is used after completing the speed and agility program as a clearance to resume training measure.
- The athlete must test with a time of at least 90% that of the unaffected side.

Objective Tests

- Physiological assessments
- Body composition tests
- Static/dynamic postural assessments
- Dynamic muscle performance testing
- Movement performance testing
- Sport-specific testing
- Others

Specific Criteria for Progression to the Next Stage to Determine Their Readiness for Football

- There are two key aspects in progress the athlete between phases.
  - Pass the eye test: Can the athlete complete the prescribed exercises with adequate control? Significant movement deficiencies in early phases will be magnified in later phases.
  - Time: Physiological adaptation to imposed load takes time. The authors recommend that a minimum of 6 weeks be devoted to the development of each muscle's physiological characteristics.

Specific Criteria for Releasing an Athlete to Unsupervised Complete Participation in Football

- Release to competition involves three steps
  - Successful completion of all scheduled training sessions, including contact training sessions, with no symptoms of pain, swelling, or instability in the knee
  - Clearance of the ligamentous stability of the knee by the treating physician
  - The athlete has complete confidence in the knee and his performance and is mentally ready to return to competition.

Recommended Ongoing Exercises

- The athlete should resume normal offseason/preseason conditioning programs after successfully completing the first season following injury. No specific exercises need to be completed; however, medical staff should closely monitor the passive and active extension in the athlete's surgically treated knee. A loss of extension motion may precipitate degenerative changes in the joint, as well as loss of quadriceps strength and a subsequent loss of performance.

Multiple-Choice Questions

QUESTION 1. What is the major concern during the first 6 weeks following surgical reconstruction?

A. Inability to bear weight on the affected leg
B. Loss of muscular strength
C. Loss of quadriceps girth
D. Excessive scar tissue formation and loss of motion

QUESTION 2. At which phase are Olympic lifts added to the rehabilitation protocol?

A. Phase 0
B. Phase I
C. Phase II
D. Phase III

QUESTION 3. What is the reported occurrence of ACL/MCL multiligamentous injuries in football?

A. 21% to 25%
B. 31% to 37%
C. 42% to 48%
D. 12% to 16%

QUESTION 4. When is the athlete allowed to focus on regaining speed and agility?

A. Immediately following muscular strength development during phase II
B. Immediately following establishment of muscular firing patterns and joint mobility during phase 0
C. Immediately following completion of a running progression program during phase III
D. Immediately following the muscular endurance program during phase I

QUESTION 5. What are the two clearance tests that allow an athlete to begin the running progression steps?

A. Ability to pass the Vail Sports Test of muscular endurance, muscular power, and ability to accept eccentric load
B. Ability to Olympic squat 75% of body weight
C. A thigh girth measured at 10 cm superior to the border of the patella within 1 cm of unaffected side
D. Ability to complete a full one-legged squat on the affected leg

Answer Key

QUESTION 1. Correct answer: **D** (see Phase 0)

QUESTION 2. Correct answer: **D** (see Phase III exercises)

QUESTION 3. Correct answer: **B** (see Introduction)

QUESTION 4. Correct answer: **C** (see Phase III)

QUESTION 5. Correct answer: **C** and **D** (see Phase III)

Chapter 35

Lateral Collateral Ligament and Posterolateral Ligament Injuries

ISOLATED LATERAL COLLATERAL LIGAMENT INJURIES: INTRODUCTION

William G. Clancy, Jr, MD

Epidemiology

- Frequency: relatively uncommon
- Age: under 30 years of age
- Sex: predominantly males
- Sport: football, wrestling, soccer

Pathophysiology

Traumatic Factors

- Isolated lateral collateral ligament injuries, although not rare, are still relatively uncommon and frequently go unrecognized. The major reasons why it is infrequent is that the necessary varus force to the knee is often blocked by the opposite leg with a resulting valgus to the protecting knee.
- Wrestling, soccer and football have produced more isolated lateral collateral ligament injuries in the author's experience.
  - In wrestling this injury can occur when the referee places the wrestlers in the neutral position in which one wrestler is standing while the other is put in the kneeling position facing his opponent. At the referee's whistle, the knee-lying player shoots for the inside knee of his opponent, while at the same time his hand grasps the foot of the same knee. With the foot now fixed there can be a significant varus load applied to the opponent's knee.
  - In soccer, this injury may occur when an opposing player attempts to slide tackle the ball from a player where the ball is on the foot of the player's extended outside leg. If the opposing player's body or leg hits the inside of the player's outside leg or knee, a varus load can be applied to that knee producing injury to the lateral collateral ligament.
  - In football, isolated lateral collateral ligament injuries occur more frequently in a pile up in which the player's foot is fixed by the bodies of fallen players and his upper body is adducted away from the fixed foot producing a varus load at the knee.

Classic Pathological Findings

- Stable to varus stress at full extension
- No appreciable laxity at 30° to varus stress in first- or second-degree sprains
- Mild laxity at 30° varus stress; minimal at 0° and no palpable fibular collateral ligament in the figure-four position for a third-degree sprain

Clinical Presentation

Physical Examination

Abnormal Findings

- Minimal knee effusion
- Minimal to mild laxity at 30° knee flexion but none at full extension (Figure 35-1)
- Pain to palpation of the intact lateral collateral in the figure four position for 1° and 2° sprains
- No palpable lateral collateral ligament in a figure four position in 3° sprains
- Careful examination will localize the pain to the lateral collateral ligament, particularly when the knee is placed in a figure four position allowing for palpation of the ligament. The lateral knee pain should be isolated only to palpation of the ligament and not the

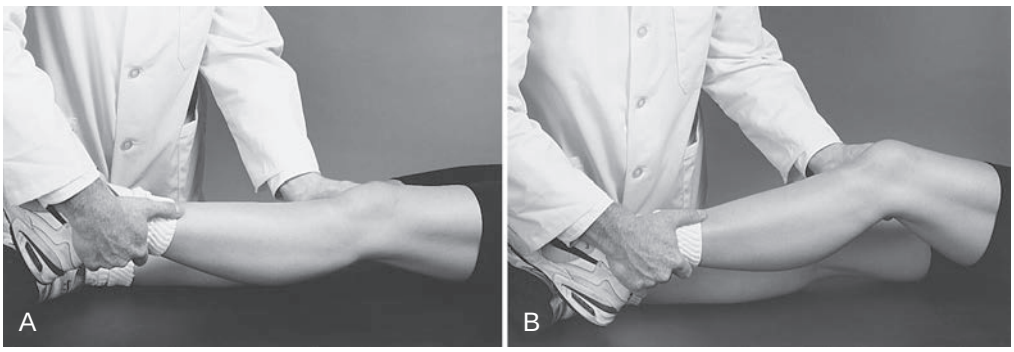

FIGURE 35-1. Varus stress lest. **A,** In extension. **B,** In flexion. Minimal to mild laxity at 30° knee flexion but none at full extension. *(From Reider B: The orthopaedic physical examination, ed 2. Philadelphia; WB Saunders, 2005.)*

anterolateral or posterolateral joint line. If there is a complete tear, the ligament will not be palpable and there should be mild increase in varus laxity at 30° of knee flexion but no appreciable laxity at full extension. Gollehon et al[1] in their report of sectioning of only the lateral collateral ligament found that there was only a 1° to 4° increase in external rotation at 30° of knee flexion and that varus laxity at 30° of knee flexion only increased from 1 to 4 mm. This study appears to correlate with our clinical findings that there is no appreciable laxity at 0° and 30° of knee flexion in isolated first and second degree lateral collateral ligament sprains. In isolated third degree sprains there should be only mild increase in varus laxity at 30° of knee flexion and minimal if at all at full extension. If there is moderate laxity at 0° and 30° of knee flexion this would suggest that there is also at least some injury to the posterolateral structures and perhaps to the cruciate ligaments.

- Varus stability is evaluated in the horizontal plane at 0° and 30° of flexion and should be equal to that of the opposite leg. External tibial rotation is measured at 30° and 90° of knee flexion. If the injury also involves a complete tear of the posterior cruciate ligament there is a marked increase in external rotation at 90° as compared to the rotational laxity measured at 30° of knee flexion as noted by Gollehon et al[1] and Grood et al[2]. In those with either an acute or chronic injury the dial test, either prone or supine performed at 30° and 90°, should establish that there is a significant difference in external tibial rotation between the normal and injured knee. However, when there has been an isolated posterior cruciate ligament injury one must maintain the neutral position of the tibia when performing the dial test otherwise the posterior tibial subluxation and coupled normal tibial external rotation may appear to be greater than it is due to the increase in posterior tibial translation. If there is normal varus laxity at 0° and 30° of knee flexion one must be suspect as to whether there is a significant injury to the posterolateral structures. A reverse pivot shift test as described by Jakob[3] is usually a sign of at least a severe posterolateral injury and a possible injury to the posterior cruciate ligament. In this test the tibia is externally rotated and flexed to 90°. A valgus load is applied and maintained as the tibia is extended while maintaining the external tibial rotation. At approximately 30° knee flexion one should feel a sudden pivot and reduction of the tibia. One must make sure this pivoting produces an anatomic reduction. In some cases this pivot-like sensation could actually be an anterior tibia subluxation due not to posterolateral laxity but due to anterior cruciate insufficiency. The pivot shift test for anterior cruciate ligament insufficiency, which is the reduction of the abnormal anterior translation, occurs at the same angle of knee flexion as does the reduction of the abnormal externally rotated tibia in those with posterolateral injury.

Pertinent Normal Findings

- No or minimal knee effusion
- Negative Lachman's test and negative posterior drawer test
- No appreciable increase in external rotation at 30° and 90° of knee flexion

Imaging

(Figure 35-2)

- MRI should be able to differentiate a lateral collateral ligament tear from a meniscal injury, and can document if there is some additional injury to the posterolateral structures and cruciate ligaments.
- Roentgenography: normal
- MRI: no lateral meniscus tear
- Edema of the lateral collateral ligament with partial or complete tear of only the lateral collateral ligament

Differential Diagnosis

- Lateral meniscus tear
- Lateral side soft tissue contusion
- Some isolated lateral collateral ligament injuries are often unrecognized due to the fact that they often do not produce severe knee pain nor produce a detectable knee effusion in first- or second-degree sprains. Often the initial diagnosis is that of a possible lateral meniscus tear.
- Lastly there is another abnormal entity that involves the posterolateral corner of the knee. This author has termed this entity *functional symptomatic posterolateral laxity*.

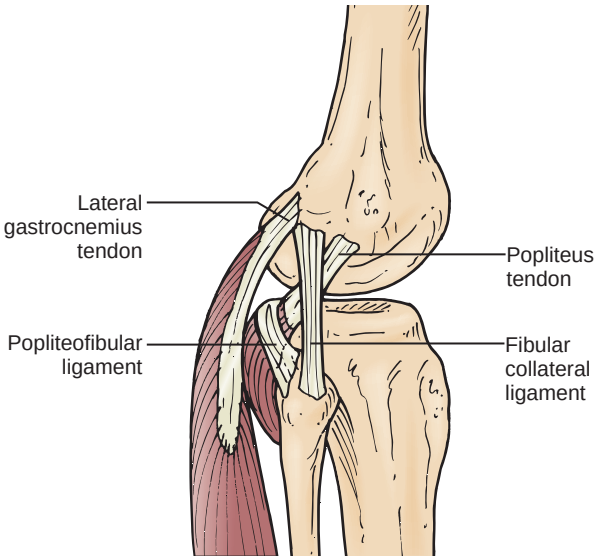

FIGURE 35-2. The isolated fibular collateral ligament, popliteus tendon, popliteofibular ligament, and lateral gastrocnemius tendon (lateral view, right knee). *(Redrawn from LaPrade RF, Ly TV, Wentorf FA, Engeretsen L: The posterolateral attachments of the knee. Am J Sports Med 31:854–860, 2003.)*

- These patients have no prior history of injury or have a history of a minimal injury.
- They all have complaints of frequent episodes of functional instability even when walking straight ahead.
- They do not have symptoms of an unstable lateral meniscus as seen in those with popliteomeniscal injuries or root avulsions and at the time of arthroscopy they do not have any signs of posterior nor posterolateral meniscal laxity.
- These patients usually have very significant increase in bilateral external tibial rotation with no increase in varus laxity at 0° or 30° of knee flexion. A dial test usually does not delineate any difference in external rotation. A reverse pivot shift test often reproduces their pain but they do not have a positive reverse pivot shift test.
- A number of these patients can reproduce their mechanism of instability. When sitting if they place the foot of the involved leg on a small stool with their knee approximately flexed 45° to 60° they can then readily sublux their tibia posterolaterally and then they can actively reduce it. This finding is similar to those patients who can voluntarily sublux their shoulder posterior or anteriorly and then voluntarily reduce it. In the shoulder, it is called electrical disassociation first described and documented in the shoulder with EMG by Rowe.[4] It appears that the biceps muscle, subluxes the tibia posterolaterally and the popliteus muscle then reduces the subluxation.

Treatment

Nonoperative Management

- The literature is extremely deficient in the treatment and follow-up of isolated lateral collateral ligament injuries. The only study in the literature is that of Kannus,[5] who reported on the follow up of nonoperative treatment of isolated grade II and grade III lateral collateral ligament sprains. He noted that all the nonoperated grade II sprains had good to excellent results whereas the non-operated grade III sprains did not fare well. The grade III sprains for the most part in this study were not isolated grade III sprains of the lateral collateral ligament as most if not all had additional injuries to the anterior cruciate and/or posterior cruciate ligament. MRI evaluations were not available at the time of this study.
- It has been the author's experience and Harner's[6] report that in surgery of the acute and chronic cases of lateral and posterolateral corner injuries that the posterior cruciate ligament must be reconstructed if injured for any successful repair of the lateral and posterolateral repairs and/or reconstructions. In the acute case all structures should be repaired or reconstructed. Nonbony avulsion injury to the popliteus tendon requires a reconstruction at the time of surgery. Thus one is creating a ligament to substitute for the popliteus muscle tendon complex. This is our treatment also for those with symptomatic physiologic posterolateral instability. The lateral collateral ligament might need an augmentation in the acute case or a graft substitute which is often needed in the chronic case. We as well as others have reported on techniques that appear to yield highly successful results. The surgical technique should include reconstruction of the popliteal ligament as it is the strongest and prime stabilizer of the posterolateral corner of the knee. In those patients with chronic instability who have a varus alignment and/or a varus thrust, a valgus osteotomy should be performed prior to or during the reconstructive procedure.

Surgical Indications

- Surgery indicated only when either cruciate ligament is torn.

Evidence

Kannus P: Nonoperative treatment of Grade II and Grade III sprains of the lateral ligament compartment of the knee. *Am J Sports Med* 17:83–88, 1989.

This is a retrospective study of 23 patients evaluated at an average 8 years after injury. There were 11 patients who were graded as having a grade II isolated lateral collateral ligament injury who were graded good or excellent. The 12 patients with a grade III injury all graded as poor. However, on review, all of these grade III injuries were not isolated but also involved either one or both cruciate ligament injuries. This paper documents that nonoperative treatment of grade II injuries did well with nonoperative treatment although the number of patients in this report was quite small. (Level IV evidence)

Grood ES, Noyes FR, Butler DL, et al: Ligamentous and capsular restraints preventing straight medial and lateral laxity in intact human cadaver knees. *J Bone Joint Surg* 58:159–172, 1981.
Markolf KL, Mensche JS, Amstutz HC: Stiffness and laxity of the knee—the contributions of the supporting structures. *J Bone Joint Surg* 58:583–594, 1976.

Nielsen S, Rasmussen O, Ovesen J, et al: Rotatory instability of cadaver knees after transection of collateral ligaments and capsule. *Arch Orthop Trauma Surg* 103:165–169, 1984.

Biomechanical studies of Grood et al., Markolf et al., and Nielsen et al. all documented that isolated sectioning of the lateral collateral ligament produced only 3° to 4° of varus laxity at 30° knee flexion and none or minimal laxity at full extension. Nielsen's also reported no increase in posterolateral rotational laxity at 30° knee flexion.

Multiple-Choice Questions

QUESTION 1. In examining a patient with suspected isolated lateral collateral ligament injury, which of the following would be the most likely clinical finding?

A. Significant knee effusion, lateral joint line pain, mildly positive Lachman's test and mild varus laxity at full extension
B. Lateral knee pain, knee effusion, pain at the anterolateral joint line, negative Lachman's test, palpable and painless fibular collateral ligament
C. Lateral and posterior knee pain, mild knee effusion, moderate varus laxity at full extension and a positive posterior drawer test
D. Lateral knee pain, no effusion, negative Lachman's and negative posterior drawer test. No varus laxity at full extension, nor at 30° flexion and pain to palpation of an intact fibular collateral ligament
E. Lateral knee pain with mild varus laxity at full extension and moderate laxity at 30° knee flexion and noticeable increase in external rotation at 30° knee flexion

QUESTION 2. Isolated sectioning of the lateral collateral ligament:

A. Produces no significant increase in varus laxity at full extension but marked increase in varus laxity at 30° knee flexion
B. Produces marked increase in varus laxity at both full extension and 30° knee flexion
C. Can produce a positive reverse pivot shift test
D. Produces only a very minimal increase in varus laxity and external rotation at 30° of knee flexion
E. Produces marked increase in external tibia rotation at 30° of knee flexion but none at full extension

Answer Key

QUESTION 1. Correct answer: **D** (see Pathophysiology)

QUESTION 2. Correct answer: **D** (see Physical Examination)

COMBINED LATERAL COLLATERAL LIGAMENT AND POSTEROLATERAL LIGAMENTOUS INJURIES: INTRODUCTION

William G. Clancy, Jr, MD

Epidemiology

- Age: usually under 30 years of age
- Sex: male more predominate than females
- Sport: football, wrestling, soccer

Pathophysiology

Intrinsic Factors

- Severe injuries to the lateral and posterolateral structures are rarely if ever isolated injuries. These injuries, although rare, are seen in contact sports mainly football, wrestling, and soccer. Severe injuries to these structures will involve injuries to either or both of the cruciate ligaments and possibly the common peroneal nerve and to a lesser extent the popliteal artery. The structures vital to lateral and posterolateral stability include the lateral collateral ligament, the popliteofibular ligament, the popliteus muscle tendon complex, the posterolateral capsule including the arcuate ligament and the biceps muscle tendon complex. These structures combine to provide lateral stability and control tibial external rotation.
- In order to understand the importance of the lateral and posterolateral structures of the knee and the role they play in functional stability one needs to know the

normal range of external tibial rotation and the biomechanical strength of the static stabilizers. Wang and Walker[1] in their study on eight cadaver knees reported that there was approximately 8° of external rotation present at 25° of knee flexion with a minimum of 6° and a maxiumum of 10°. Fukubayashi et al.[2] documented that there is a coupled translation and rotation with anterior and posterior forces applied to the knee. With a posterior force there is a coupled posterior translation and an external rotation. They noted with a 100 N load that the greatest amount of external rotation was approximately 8° at 25°, 12° at 75°, and 6° at 90° of knee flexion.

- Biomechanical studies of sectioning of the various lateral structures and the effects on external rotation have been performed by numerous authors. Nielsen et al.[3] noted that the popliteus tendon as a passive stabilizer was the prime stabilizer to posterolateral stability due to its attachments to both the arcuate ligament and the tibia as documented by Last. Nielsen's study also documented that marked posterolateral instability was impossible with an intact popliteus tendon. Gollenhon et al.[4] and Grood et al.[5] noted that sectioning of all the posterolateral structures with an intact posterior cruciate ligament produced significant increase in external rotation most notably at 30° of knee flexion and additional sectioning of the posterior cruciate ligament further increased abnormal external rotation most notably at 90° of flexion.
- A summation of the reports in the literature on the biomechanical strengths of the lateral structures noted that the load to failure of the lateral collateral ligaments in 49 knees (age range 40 to 93 years) was 513 N (range 295 to 746 N). The maximum load to failure for the popliteofibular ligament in 37 knees (age range 40 to 93 years) was 132 N (range of 42 to 298 N). This structure which is a branch of the popliteus tendon appears to be the weakest of all the lateral stabilizers but is still an important stabilizer. The maximum load to failure for the popliteus muscle tendon complex in 8 knees (average age of 57 years) was 700 N. The popliteus muscle tendon complex is the strongest static stabilizer but of more importance is its strong muscular contraction counteracting excessive posterolateral rotation.

Extrinsic Factors

- Pile-up in football
- Takedown from the neutral position in wrestling
- Sliding tackle in soccer

Traumatic Factors

- A varus blow to the knee with a planted foot or an anterior varus blow to the knee with a planted foot

Classic Pathological Findings

- Anterior cruciate and/or posterior cruciate ligament with injury to the lateral collateral ligament, popliteal fibular ligament with injury to the popliteus muscle tendon complex, biceps tendon, common peroneal nerve, and possibly the popliteal artery

Clinical Presentaition

History

- A contact injury with a varus load to the knee either flexed or extended with the foot planted with ensuing severe lateral knee pain

Physical Examination

Abnormal Findings

- Marked varus laxity at 0° flexion
- Positive Lachman's test and/or a positive posterior drawer test. There may be neurologic findings such as inability to dorsiflex the foot and toes and loss of sensation on the lateral side of the leg and dorsum of the foot

Pertinent Normal Findings

- Usually intact medial structures without valgus laxity at 30° and 0° of flexion

Imaging

- MRI findings
  - Tear of the ACL and/or PCL
  - Tears of the lateral collateral ligament, the popliteal fibular ligament, lateral capsule and injury to the popliteus muscle tendon complex and the biceps tendon

Differential Diagnosis

- This entity should not be confused with any other except in those with open physeal growth plates, where a physeal fracture may also be present.

Treatment

Surgical Indications

- Reconstruction of the appropriate cruciate ligaments
- Repair and when necessary augment or reconstruct the appropriate lateral stabilizing structures especially the popliteus tendon complex
- Valgus tibial osteotomy in chronic cases with varus alignment or varus thrust prior to or at the time of reconstruction

Aspects of History, Demographics, or Exam Findings that Affect Choice of Treatment

- If there is a physeal fracture it should be stabilized first, after which the soft tissue injuries should be repaired or reconstructed.

Aspects of Clinical Decision Making When Surgery Is Indicated

- First the anterior and/or posterior cruciate ligaments need to be reconstructed and then the lateral and posterolateral structures need to be stabilized at the same operation and not staged. The common peroneal nerve needs to be explored as the nerve curves around the fibular neck and the fibrotic band under the anterolateral muscles needs to be released when present.

Evidence

BIOMECHANICAL

Multiple-Choice Questions

QUESTION 1. In order to produce a reverse pivot shift there must be complete disruption of the:

A. Fibular collateral ligament
B. Fibular collateral ligament and the anterior cruciate ligament
C. Fibular collateral ligament and popliteomeniscal ligaments
D. Isolated sectioning of the posterior cruciate ligament
E. Fibular collateral ligament, popliteofibular ligament and popliteus tendon posterolateral capsule/arcuate ligament

QUESTION 2. In those patients with chronic lateral, posterolateral, and posterior cruciate ligament injuries one needs to treat:

A. Only the posterior cruciate ligament
B. Only the posterolateral structures
C. Only the posterior cruciate ligament and the posterolateral capsule
D. Only the popliteus muscle complex
E. The posterior cruciate ligament and all of the posterolateral structures

QUESTION 3. In those patients with an acute combined anterior cruciate, posterior cruciate and lateral and posterolateral corner injuries without popliteal or peroneal nerve injury the most appropriate treatment is:

A. No operative management
B. Reconstruct the anterior cruciate ligament first then at a later date surgically treat the other injuries
C. Reconstruct the posterior cruciate first then at a later date surgically treat the other injuries
D. Reconstruct the anterior and posterior cruciate ligaments first and at a later date treat the posterolateral corner injuries
E. Reconstruct the anterior cruciate, posterior cruciate ligament and the lateral and posterolateral corner injuries all at the same time

Answer Key

QUESTION 1. Correct answer: **E** (see Pathophysiology)

QUESTION 2. Correct answer: **E** (see Pathophysiology)

QUESTION 3. Correct answer: **E** (see Pathophysiology)

NONOPERATIVE REHABILITATION OF LATERAL COLLATERAL LIGAMENT SPRAINS

William G. Clancy, MD, Kevin E. Wilk, PT, DPT, and Leonard C. Macrina, MSPT, SCS, CSCS

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- Initial focus of the rehabilitation should work to decrease pain and swelling while minimizing the effects of immobilization and muscular atrophy.
- Never overstress the healing tissue.
- Allow enough time for adequate healing to occur which will allow the athlete to return to sports without long-term deleterious effects

Phase I (weeks 0 to 4 to 6 postinjury)

Goals

- Early protected ROM
- Prevent quadriceps atrophy
- Decrease effusion/pain

Protection

- The knee is protected by placing the knee in a brace, typically locked at 0°, while walking on crutches to slightly unweight the injured extremity.

Management of Pain and Swelling

- The patient is instructed to ice and elevate the extremity for 20 minutes every hour throughout the first 2 weeks or until adequate swelling control is attained. Icing should be performed in full knee extension to prevent a flexion contracture from forming.
- A compression sleeve or ace wrap may be utilized to keep swelling to a minimum.
- Weight bearing may be allowed immediately, however, in a brace locked at 0° and while using crutches.
- Analgesic and antiinflammatory medications may be utilized to decrease pain and swelling.
- Low-level laser therapy (cold laser) may be utilized to improve tissue healing[1-3] (Figure 35-3).

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- The rehabilitation specialist may begin patella mobilizations immediately to tolerance. Also, gentle manual passive range of motion of the knee may be initiated to neuromodulate pain and aid in collagen alignment of the healing ligamentous tissue.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- The athlete may begin some gentle calf and hamstring stretching to maintain flexibility and assist in maintaining full knee extension.

Other Therapeutic Exercises

- Neuromuscular electrical stimulation to the quadriceps is initiated immediately during straight leg raises.
- Hip adduction and external and internal rotation may also be performed. Sidelying hip abduction should be avoided to decrease stresses on the lateral knee soft tissue structures.
- Ankle, hip, and core strengthening may be initiated as long as there are no deleterious stresses on the lateral knee structures.
- Hamstring and calf stretching may be performed to maintain lower leg flexibility

Activation of Primary Muscles Involved

- Quadriceps, hip abductors, adductors, extensors, external rotators

Sensorimotor Exercises

- Passive/active joint repositioning may be utilized to initially improve joint proprioception and awareness.

Open and Closed Kinetic Chain Exercises

- Straight leg raises, four-way ankle with resistance tubing

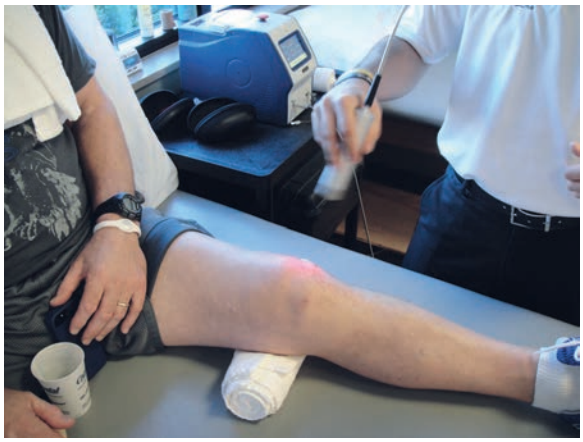

FIGURE 35-3. Low level laser therapy to promote a healing response at the site of the injury.

Neuromuscular Dynamic Stability Exercises

- Forward/backward weight shifting onto the involved extremity followed by lateral weight shifting as long as there's no lateral knee pain. Single leg stance activities may be initiated as tolerated to further challenge the patient's dynamic stability.

Functional Exercises

- Crutch training while in the brace locked at 0 degrees.

Milestones for Progression to the Next Phase

- Minimal pain or swelling
- Physical exam shows minimal to no lateral knee opening with varus stressing
- Good quadriceps control with straight leg raises with no quadriceps lag
- Voluntary quadriceps activation

Phase II (weeks 6 to 10)

Goals

- Full painless ROM
- Restore strength
- Ambulation without crutches

Protection

- Crutches no longer needed
- Brace used with walking but unlocked to available range of motion
- Progress to hinged-upright brace (DonJoy Playmaker) for medial/lateral stability

Management of Pain and Swelling

- Continue ice, compression, and elevation particularly after the rehabilitation visit. May initiate moist hot packs before the treatment to bring blood to the area and improve soft tissue mobility. PROM also utilized to decrease pain and stiffness.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Continue to progress passive range of motion to relative tolerance with careful attention to avoid over stressing the lateral knee.

Soft Tissue Techniques

- Soft tissue mobilization to the quadriceps and hamstrings may aid in improving flexibility. Cross friction massage to the LCL may aid in tissue healing and collagen alignment.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- The athlete may work on a complete stretching program for the quadriceps, hamstring, iliotibial band, and gastrocnemius-soleus complex.

Other Therapeutic Exercises

- Progress weight-bearing strengthening exercises
  - Bicycle
  - Leg press (0° to 80°)
  - Knee extensions 60° to 0°
  - Multi Hip machine
  - Hip external/internal rotation
  - Wall squats 0° to 60°

TIMELINE 35-1: **Nonoperative Rehabilitation of Lateral Collateral Ligament Sprains**

PHASE I (Maximal Protection, weeks 1 to 6)		
Week 1	**Week 2**	**Week 6**
• Ice, compression, elevation • Knee hinge brace non-painful ROM; if needed • Crutches, weight bearing as tolerated • Passive range of motion/active assistive range of motion to maintain ROM • Electrical muscle stim to quads (8 h a day) • Isometrics quads: quad sets, straight leg raises (flexion)	• Continue above exercises • Quadriceps sets • Straight leg raises (flexion, adduction) • Abduction isometrics • Hamstring isometric sets • Hip ER/IR • Sidelying clams • Well leg exercises • Initiate minisquats	• Continue above exercises • Crutches—weight bearing as tolerated • ROM as tolerated • Eccentric quadriceps work • Bicycle for ROM stimulus • Resisted knee extension with electrical muscle stimulation 60°-0° • Initiate hip abduction as symptoms allow • Initiate leg press 0°-80° • Brace worn at night, brace during day as needed • Weight shifts • Single leg balance

- Sidelying clams
- Lateral step-downs
- Resisted lateral walking (monster walks)—resistance should be just proximal to the knee joint and closely monitored for pain
- Single-legged balance on foam
  - Light perturbations

Activation of Primary Muscles Involved

- Weight-bearing strengthening to include the quadriceps, hamstring, hip musculature with particular attention to the abductors, extensors, and external rotators.

Sensorimotor Exercises

- Tilt board minisquat, single leg stance activities on unstable surfaces, light perturbation training

Open and Closed Kinetic Chain Exercises

- See abovementioned exercises

Techniques to Increase Muscle Strength, Power, and Endurance

- See abovementioned exercises

Neuromuscular Dynamic Stability Exercises

- As mentioned, perturbation training on unstable surfaces once the athlete demonstrates good leg control with ambulating and demonstrates adequate baseline strength

Functional Exercises

- Normalize gait; progressively challenging single leg balance activities; eccentric quadriceps strengthening. May initiate aquatic therapy including jogging and lateral movements

Sport-Specific Exercises

- See combination of above exercises

Milestones for Progression to the Next Phase

- Full, pain-free PROM and AROM
- Stable knee without excessive varus laxity on physical examination
- >4+/5 MMT for involved lower extremity musculature including the quadriceps, hamstrings, gluteals, hip rotators

Phase III (weeks 10 to 16)

Goals

- Increase strength and power

Protection

- Hinged knee brace (Figure 35-4) or a custom knee brace to protect the lateral collateral ligament

Management of Pain and Swelling

- Cryotherapy as needed in response to each treatment session

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Continue to maintain passive range of motion to full and work flexibility for the entire lower body.

TIMELINE 35-1 Nonoperative Rehabilitation of Lateral Collateral Ligament Sprains (Continued)

PHASE II (Intermediate Phase, weeks 6 to 10)	PHASE III (Advanced Phase, weeks 10 to16)	PHASE IV (Maintenance Program)

• Continue strengthening program with PRE's
• Continue electric muscle stim to quads during isotonic strengthening
• Continue ROM exercise
• Emphasize closed kinetic chain exercises; lunges, squats, lateral lunges, wall squats, lateral step-ups
• Bicycle for endurance
• Water exercises, running in water forward and backward
• Full ROM exercises
• Flexibility exercises, hamstrings, quads, IT Band, etc.
• Proprioception training (balance drills)
  • Weight shifts
  • Tilt board squats
  • Single leg balance on unstable surface
• Stairmaster/elliptical for cardiovascular work
	• Continue strengthening program
	  • Wall squats
	  • Vertical squats
	  • Lunges
	  • Lateral lunges
	  • Step ups
	  • Leg press
	  • Knee extension
	  • Hip abd/adduction
	  • Hamstring curls
	  • Emphasis:
	  • Functional exercise drills
	  • Sport cord lunges, cone drills
	  • Fast speed isokinetics
	  • Eccentric quads
	  • Isotonic hip add, medial hamstrings
	• Isokinetic test
	• Proprioception training
	• Endurance exercise
	• Stationary bike 30 to 40 min
	• Initiate agility program, sport-specific activities
		• Continue isotonic strengthening exercises
		• Continue flexibility exercises
		• Continue proprioceptive activities

FIGURE 35-4. Hinged knee brace (Playmaker, DJO Global, Vista, California) used to give lateral stability as the patient progresses through the rehabilitation program.

Soft Tissue Techniques

- For lower extremity musculature, if lacking full excursion a foam roller may be utilized as an adjunct treatment to release trigger points

Stretching and Flexibility Techniques for the Musculotendinous Unit

- See above

Other Therapeutic Exercises

- Continue with machine weights to entire lower body musculature
- Progressive body weight exercises including
  - Forward and lateral lunges
- Sports cord exercises to work on NM control, dynamic stability and hand-eye coordination (Figure 35-5)
- Core stabilization

Activation of Primary Muscles Involved

- Continue to progress complete lower body strengthening to quadriceps, hip musculature

Sensorimotor Exercises

- Perturbation training on unstable surfaces
- BOSU squats (Figure 35-6)
- Single leg stance drills including:
  - Star drill
  - Ball toss

Open and Closed Kinetic Chain Exercises

- See previous strengthening exercises

FIGURE 35-5. Sport cord lateral lunging while catching a ball to promote dynamic stability, neuromuscular control and hand-eye coordination.

FIGURE 35-6. BOSU squat on an unstable surface while catching a basketball.

Techniques to Increase Muscle Strength, Power, and Endurance

- Progressive resistance exercises, aerobic conditioning including stationary bike, elliptical, swimming and pool running

Neuromuscular Dynamic Stability Exercises

- See above

Plyometrics

- May initiate light plyometric exercises on leg press toward the end of this phase depending on strength and tissue healing
- Two-legged hops in place
- Two-legged hops forward/back emphasizing landing technique

Functional Exercises

- Pool exercises including swimming, running, antigravity treadmill as long as no increase in symptoms.

- Progression to treadmill running as long as the patient completes previous functional exercises without difficulty or pain.

Sport-Specific Exercises

- See functional exercises above

Milestones for Progression to the Next Phase

- Full PROM and AROM, pain free
- No effusion through joint line and suprapatella girth measurements
- No lateral instability with clinical examination
- Muscle strength 85% contralateral side per isokinetic testing
- No tenderness to palpation over the LCL
- No changes in posterolateral laxity
  - May use Dial test
  - Varus laxity testing at 0° and 25°
- Quadriceps peak torque to body weight 60% to 65% on isokinetic testing

Phase IV (weeks 16+)

Protection

- Functional knee brace if prescribed by the MD

Management of Pain and Swelling

- As needed. See previous sections

Techniques for Progressive Increase in Range of Motion

Soft Tissue Techniques

- Soft tissue mobilization as needed to lower extremity musculature as the patient progresses through higher level strengthening to diminish delayed onset muscle soreness (DOMS)

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Dynamic flexibility exercises before the athlete begins workouts.
- Static stretching may be employed as needed after exercising.

Other Therapeutic Exercises

- Continue total leg strengthening with progressive resistive exercises
- Gradually progress running on treadmill and slowly progressing to field work
- Initiate agility drills to focus on cutting and start-stop drills

Activation of Primary Muscles Involved

- Quadriceps, gastrocnemius-soleus complex, hip musculature

Sensorimotor Exercises

- Continued balance activities and perturbation training on unstable surfaces, incorporating functional activities including throwing and catching

Open and Closed Kinetic Chain Exercises

- Continue aforementioned exercises and progress plyometrics to include box jumps, skip jumps, and scissor jumps to improve power and endurance.
- Verbal cueing is utilized to ensure the athlete is landing correctly and with even weight distribution bilaterally to prevent compensation.

Techniques to Increase Muscle Strength, Power, and Endurance

- See above

Neuromuscular Dynamic Stability Exercises

- See above

Plyometrics

- See above

Functional Exercises

- Progression through running program depending on sport (Box 35-1)
- Agility drills
  - Lateral cariocas
  - Figure of 8's
  - Shuttle runs
  - Interval sprinting program
  - Specific sport drills and activities

Sport-Specific Exercises

- On field drills simulating the patient's sport

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- Full Strength 5/5 manual muscle test
- Full PROM and AROM
- Isokinetic testing criteria:
  - Quadriceps torque to body weight ratio ≥ 65%
  - Hamstrings/quadriceps ratio within 70%
  - Bilateral comparison of quadriceps within 90%
  - Bilateral hamstrings within 100%
  - Acceleration rate at 0.2 seconds (80% of quads peak torque)
- No pain with functional activities including running, jumping and cutting
- >85% proprioception on Biodex Stability System

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or more Intensive Intervention

- Continued pain
- Varus laxity that has progressed beyond 1+ end feel

BOX 35-1 Interval Running Program

- FORWARD RUNNING: Run at _____% of maximal effort for a distance of _____ feet straight ahead. Perform _____ times.
- BACKWARD RUNNING: Run backwards at _____% maximal effort for a distance of ___ feet. Repeat ____ times.
- SIDE SHUFFLE: Begin by standing side-ways, step out with the lead foot and follow with the back foot in a side-stepping motion. Perform at ____% of maximal effort for a distance of _____ feet. Repeat in opposite direction. Perform _____ times in each direction.
- START & STOP: Run straight forward at ____% of maximal effort for a distance of ____feet then stop as quickly as possible. Perform ____times.
- FIGURE of 8: Place two cones _____ feet apart. Start by standing in between cones and run a circle around one cone, then back to the starting position. Continue around opposite cone in a figure of 8 pattern. Perform at _____% maximal effort. Perform ____ times.
- 45-DEGREE CUTS: Run at ____% maximal effort for a distance of ____ feet, plant the involved leg and change direction such that the subsequent path you are running makes a 45-degree angle with the original path. Repeat the process while cutting on the uninvolved extremity. Perform ____ times.
- 90-DEGREE CUTS: Run at ____% maximal effort for a distance of ____ feet, plant the involved leg and change direction such that the subsequent path you are running makes a 90-degree angle with the original path. Repeat the process while cutting on the uninvolved extremity. Perform ____ times.
- FOUR-CORNERS DRILL: Place four cones in a square at a distance of ____ feet apart. Run forward at _____% maximal effort. Plant on the involved leg while maintaining the same body direction, then side step to the next cone. Backpedal to the next cone and another side step to the final cone. Repeat ____ times.

Indoor Interval Running Program

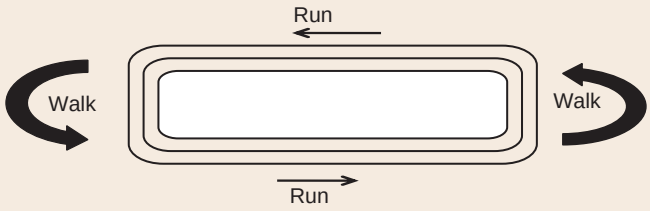
- Jog ~18 laps around the basketball court (~1 mile). Stop immediately if you begin to limp or feel any pain. If pain-free:
- Run____ lengths of the gym at ½ speed. If no pain, then:
- Run____ lengths of the gym at ¾ speed. If no pain, then:
- Run____ lengths of the gym at full speed. If no pain, then:
- Run____ lengths, cutting by planting on involved leg, at full speed. If pain free:
- Perform 10 minutes of running or jumping drills related to your sport. When you have completed the entire program, you are ready to return to competition.
  - If you do not complete the entire program on a particular day, you should begin at the first step the following day.
  - Each running session must be followed by a good stretching program for each major muscle group of the lower extremities, along with ice application for 15 minutes.

Outdoor Interval Running Program

- Jog 1 mile. Stop immediately if you begin to limp or feel any pain. If pain-free:
- Perform six 80-yard sprints at ½ speed. If no pain or limp:
- Perform six 80-yard sprints at ¾ speed. If no pain or limp:
- Perform six 80-yard sprints at full speed. If no pain or limp:
- Perform six 80-yard sprints with cutting at ½ speed. If no pain:
- Perform six 80-yard sprints with cutting at ¾ speed. If no pain:
- Perform six 80-yard sprints with cutting at full speed. Always plant on the outside foot to cut. If no pain:
- Perform 10 minutes of running and/or jumping drills related to your sport. When the entire program has been completed, you are ready to return to competition.
  - If you do not complete the entire program on a particular day, you should begin at the first step the following day.
  - Each running session must be followed by a good stretching program for each major muscle group of the lower extremities, along with ice application for 15 minutes.

Outdoor Track Interval Running Program

- Run on an outdoor track. Run at ____% of maximum on the straightaways and slow to a walk when going around the curves. Perform ____ laps.



- Unable to return to sports after 3+ months of nonoperative treatment

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Able to perform all activities without increase in symptoms
- Satisfactory physical examination
- Clearance by physician

Evidence

Bushnell BD, Bitting SS, Crain JM, et al: Treatment of magnetic resonance imaging documented isolated grade III lateral collateral ligament injuries in national football league athletes. *Am J Sports Med* 38:86–91, 2010.

This cohort study looked at nine professional football players who had sustained LCL sprains between 1994 and 2004 utilizing the NFL's Injury Surveillance System database. Nonoperative management (n = 5) resulted in a more rapid return to play than the operative group (n = 4) and were able to continue playing for 4.4 additional seasons (nonoperative) versus 2.8 seasons (operative) p = .253. (Level III Cohort Study)

Meister BR, Michael SP, Moyer RA, et al: Anatomy and kinematics of the lateral collateral ligament. *Am J Sports Med* 28:869–878, 2000.

This cadaveric study looked at the anatomy and kinematics of the lateral collateral ligament in 10 unembalmed limbs and 20 isolated femurs and fibulas. On average the ligament measured 66 mm in length (range, 5 to 74 mm) while the average greatest dimension of its thin middle portion was 3.4 mm (range 3 to 4 mm).

Multiple-Choice Questions

QUESTION 1. The *initial* focus of rehabilitation after an LCL sprain is:

A. Immobilization of the lower extremity for 4 to 6 weeks to allow for appropriate healing
B. Prevention of full knee extension as to not overstress the ligament
C. Decreasing pain and swelling and allowing time for healing to occur
D. Weight bearing strengthening exercises to increase muscle strength.

QUESTION 2. During Phase I of rehab for an LCL sprain, all of the following are appropriate therapeutic exercises for the patient, with the *exception* of:

A. Electrical stimulation of the quadriceps musculature
B. Sidelying hip abduction
C. Hamstring and calf stretching
D. Forward/backward weight shifts

QUESTION 3. Choose the TRUE statement from the following:

A. During Phase II of rehab, the patient's knee brace should be locked in full knee extension at all times.
B. In order to progress to Phase II, the patient must have 5/5 MMT for lower extremity musculature.
C. The time frame of Phase II consists of weeks 3 to 6.
D. During Phase II, light perturbation training and proprioception exercises on unstable surfaces can be initiated.

QUESTION 4. Light plyometric exercises can be initiated with your patient, if the patient demonstrates adequate strength and tissue healing, at approximately what stage during rehabilitation?

A. Weeks 4 to 6
B. Never before week 16
C. Weeks 8 to 10
D. Weeks 14 to 15

QUESTION 5. Identify below one of the correct criterion for progressing the patient to sport specific training and conditioning.

A. Greater than 60% proprioception on Biodex Stability System
B. The patient is able to complete 1 mile of treadmill running pain free in under 10 minutes and 30 reps pain free on the leg press machine with 150 lb
C. Isokinetic test within 15% of contralateral extremity at 180 degrees and 300 degrees
D. A score of Greater than 70/80 on the Lower Extremity Function Scale

Answer Key

QUESTION 1. Correct answer: **C** (see Guiding Principles of LCL Sprain box)

QUESTION 2. Correct answer: **B** (see Phase I)

QUESTION 3. Correct answer: **D** (see Phase II)

QUESTION 4. Correct answer: **D** (see Phase III)

QUESTION 5. Correct answer: **C** (see Phase IV)

POSTOPERATIVE REHABILITATION AFTER POSTEROLATERAL CORNER REPAIR OR RECONSTRUCTION

William G. Clancy, MD, Kevin E. Wilk PT, DPT, and Leonard C. Macrina, MSPT, SCS, CSCS

Indications for Surgical Treatment

- MRI confirming soft tissue lesions
- Physical exam demonstrating excessive posterolateral laxity
- Functionally limited

Brief Summary of Surgical Treatment

- If either of the cruciate ligaments are injured which is almost always present, they need to be addressed before proceeding with acute repair of the posterolateral structures

Major Surgical Steps

- Tourniquet is applied but almost never need to be inflated
- Incision acute or chronic
- With the knee in approximately 30° of flexion
- Starting longitudinally approximately above the lateral femoral epicondyle then curved distally at the lateral femoral epicondyle and carried inferiorly between the anterior fibular head and Gerde's tubercle
- The iliotibial track is then split in the same fashion
- This gives exposure to the biceps tendon, posterolateral capsule, fibular collateral ligament and the peroneal nerve injury
- Palpate the common peroneal nerve as it curves around the fibular neck and free up the nerve both proximally and distally. Frequently there is a strong and tight fascial band posterior to the anterolateral muscular insertion which must be freed so that nerve compression does not occur post surgery from swelling which can lead to a foot drop 24 to 48 hours post surgery

Acute Injury

- A small longitudinal incision is made over the popliteus fovea to inspect the insertion of the popliteus tendon.
- If avulsed from the insertion, then direct repair with a suture anchor should suffice.
- If irreparable damage is present, then a popliteal ligament must be created (see chronic repair).
- The biceps tendon is explored and repaired as well as the posterolateral capsule if there is significant injury.
- If the posterolateral capsule is repaired, this must be carried out at or near full extension, and full extension is mandatory after repair.
- The fibular collateral ligament is repaired and may be supplemented with graft when necessary.

Brief Summary of Surgical Treatment for Chronic Posterolateral Knee Injury

- Tourniquet is applied but rarely needs to be inflated.
- Cruciate ligament(s) need to be addressed before posterolateral reconstruction.
- Knee varus alignment need to be addressed as to whether a valgus osteotomy needs to be performed before considering a soft tissue reconstruction.
- Surgical incision same as described for acute repair.
- The three major components that need to be addressed are:
  - popliteus muscle tendon complex
  - posterolateral capsule
  - fibular collateral ligament
- In severe chronic posterolateral instability the critical structure to be addressed is the popliteus tendon complex which is either irreparably injured or is nonfunctioning.
- A half of an Achilles tendon allograft with bone or a 8 mm quadriceps autograft with bone can be utilized to create a popliteal ligament which will be physiometric through the full range of motion by our studies.
- A drill hole 8 to 10 mm wide and 20 mm in depth is made at the femoral insertion of the popliteus insertion at the anterosuperior aspect of the popliteus fovea.
- An 8 to 10 mm tunnel is then made starting just below Gerde's tubercle after elevating the insertions of the anterolateral muscles and it should exit on the inferior tibial plateau half way between the PCL insertion and the posteromedial edge of the fibular head.
- The bone portion of the graft is placed in the femoral drill hole and held with an interference screw. The graft is then pulled into the knee joint through the popliteus hiatus and joint capsule exiting along the normal path of the popliteus hiatus and then through the tibial tunnel posterior to anterior. A graft passer will facilitate this.
- A new fibular collateral ligament can be created but utilizing the other half of the Achilles tendon allograft or a gracilis tendon autograft.
- A drill hole 8 to 10 mm wide and 20 mm in depth is made just at the inferior most aspect of the lateral femoral condyle (the FCL inserts just inferior to the LFC) and fixed with an interference screw.
- A second drill hole is made through the fibular head.
- The graft is then pulled through the previously drilled fibular tunnel posterior to anterior and can be fixed in the tunnel or brought up to the lateral femoral epicondyle and fixed with a suture anchor, and then the two bands are sutured together.
- If the posterolateral capsule is severely lax, it can be advanced superiolaterally and fixed with suture anchors making sure the knee has full extension.

Comments

- The popliteus fibular ligament is not addressed in our procedure for several reasons. First, it is only a branch of the popliteus tendon and is the weakest of all the structures. Secondly, in those patients whom we did add a popliteofibular ligament reconstruction, we found no clinical differences in our results.
- Postoperatively we utilize a spring loaded knee brace (Dynasplint), maintaining full extension and allow progress weight bearing. The brace is utilized to help contain excessive posterolateral knee rotation.

Before Surgery: Overview of Goals, Milestones, and Guidelines[1]

GUIDING PRINCIPLES OF POSTOPERATIVE REHABILITATION

- Diminish pain and swelling in the early phases.
- Never overstress the healing tissue.
- Dynasplint brace for 6 weeks to minimize stress on the healing soft tissues.
- Gradual return to function through progressive ROM, WB and strengthening exercises.
- Control forces onto the lateral and posterolateral corner.

Goals

- Diminish pain and swelling
- Normalize range of motion
- Activate quadriceps
- Protect posterolateral corner structures of the knee

Management of Pain and Swelling

- Elastic wrap or knee sleeve to reduce swelling

Exercises

- Ankle pumps
- Passive knee extension (gradual progression)
- Passive knee flexion to tolerance
- Straight leg raises (three-way, flexion, abduction), pillow squeezes
- Quadriceps setting
- Closed kinetic chain exercises: minisquats, lunges, step-ups

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Electrical muscle stimulation to quadriceps during voluntary quadriceps exercises (4 to 6 hours per day)

Neuromuscular Dynamic Stability Exercises

- Eliminate quad avoidance gait
- Retro stepping drills

[1]*Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

Cryotherapy/Elevation

- Apply ice 20 minutes of every hour, and elevate leg with knee in full extension (knee must be above heart)

Patient Education

- Review postoperative rehabilitation program.
- Review instructional video (optional).
- Select appropriate surgical date.

Phase I: Immediate Postoperative Period (days 0 to 14)

Goals

- Decrease pain and swelling through cryotherapy, PROM, and electrotherapeutic modalities.
- Obtain immediate extension to 0°.
- Instruct on gait training while in locked brace in brace and weight-bearing as tolerated.
- Normalize patella mobility.
- PROM to 90° flexion.

Clinical Pearl

During this phase, it is imperative to obtain full knee extension immediately while limiting hyperextension, which may put unwanted stresses on the healing tissues. Also, the patient must avoid active hamstring activity for 8 weeks. Finally, a Dynasplint brace is used during ambulating to prevent posterior tibial sag.

Protection

- The knee is protected by placing it in a Dynasplint brace locked at 0°.
- Immediate weight-bearing is allowed to tolerance.
- The patient typically ambulates in crutches for 2 to 3 weeks to decrease stress on the healing structures.

Management of Pain and Swelling

- The patient is instructed to ice and elevate the extremity for 20 minutes every hour throughout the first 2 weeks or until adequate swelling control is attained. Icing should be performed in full knee extension to prevent a flexion contracture from forming. A vasopneumatic compressive device (Figure 35-7) may be utilized to simultaneously decrease swelling and pain.
- A compression sleeve or ace wrap may be utilized to keep swelling to a minimum.
- Analgesics and antiinflammatory medications may be utilized to decrease pain and swelling.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- The rehabilitation specialist may begin patellar mobilizations immediately to tolerance.

TIMELINE 35-2: **Postoperative Rehabilitation After Posterolateral Corner Repair or Reconstruction**

PHASE I (Immediately Postoperative, weeks 0 to 2)

Week 1

Day 1

- Protection: brace/immobilizer (Dynasplint) applied to knee, locked at 0°of flexion for ambulation and sleeping
- Weight bearing: two crutches, weight bearing as tolerated
- Exercises:
  - Ankle pumps
  - Overpressure into passive knee extension
  - Active and passive knee flexion (90° by Week 2
  - Straight leg raises (flexion, adduction); *no* abduction
  - Quadriceps isometric setting
  - Hamstring stretches
  - Closed kinetic chain exercises: weight shifts
- Muscle stimulation: use muscle stimulation during active muscle exercises (4 to 6 hours per day)
- Passive motion: as needed, 20° to 60° (as tolerated and as directed by physician) maintain anterior tibial force during passive knee flexion
- Ice and evaluation: ice 20 minutes out of every hour and elevate with knee in full extension

Days 2 to 4

- Protection: EZ Wrap brace/immobilizer, locked at 0° extension for ambulation
- Weight bearing: two crutches, weight bearing as tolerated
- Range of motion
  - Remove brace, perform range of motion exercises 6 to 8 times per day
  - Perform frequent bouts of ROM to regain knee flexibility
- Exercises:
  - Gentle overpressure into extension
  - Emphasize restoring knee extension
  - Patellar mobilization
  - Ankle pumps
  - Straight leg raises, pillow squeezes
  - Minisquats and weight shifts
  - Quadriceps isometric setting
- Muscle stimulation: electrical muscle stimulation to quads (6 hours per day)
- Passive motion: 20° to 70° with anterior tibial force
- Ice and evaluation: ice 20 minutes out of every hour and elevate leg with knee in full extension

Days 5 to 7

- Protection: brace/immobilizer, locked at 0° extension for ambulation and unlocked for sitting, etc.
- Weight bearing: two crutches, weight bearing as tolerated
- Range of motion: remove brace to perform range of motion exercises 6 to 8 times per day, knee flexion 75° by day 5, approximately 80° by day 7
- Exercises:
  - Multi-angle isometrics at 90° and 60° of flexion (knee extension)
  - Knee extension (90° to 40°)
  - Patellar mobilization (5 to 8 times daily)
  - Ankle pumps
  - Straight-leg raises, pillow squeezes
  - Minisquats and weight shifts as tolerated
  - Quadriceps isometric setting
  - Proprioception and balance activities
- Neuromuscular training/proprioception:
  - OKC passive/active joint repositioning at 90°, 60°
  - CKC squats and weight shifts
- Muscle stimulation: electrical muscle stimulation (continue 6 hours daily)
- Passive motion: 0° to 90°, as needed
- Ice and elevation: ice 20 minutes of every hour and elevate leg with knee full extension

*At the end of week two, recheck with MD to determine whether extension can be progressed faster.

TIMELINE 35-2 Postoperative Rehabilitation After Posterolateral Corner Repair or Reconstruction (Continued)

	PHASE II (Early Rehabilitation, weeks 2 to 4)	
Week 2	**Week 2***	**Week 3**

• Protection: brace/immobilizer, locked at 0° extension for ambulation
• Weight bearing: two crutches, partial weight bearing to weight bearing as tolerated
• Range of motion: remove brace to perform range of motion exercises 6 to 8 times per day, knee flexion 90° by day 14
• Exercises:
  • Multi-angle isometrics at 90° and 60° (knee extension)
  • Knee extension 90° to 40°
  • Patellar mobilization (5 to 8 times daily)
  • Ankle pumps
  • Straight leg raises, pillow squeezes
  • Minisquats and weight shifts
  • Quadriceps isometric setting
  • Proprioception and balance activities
• Neuromuscular training/proprioception:
  • OKC passive/active joint repositioning at 90°, 60°
  • CKC squats and weight shifts
• Muscle stimulation: electrical muscle stimulation (continue 6 hours daily)
• Passive motion: 0° to 90°, as needed
• Ice and elevation: ice 20 minutes of every hour and elevate leg with knee full extension
	• Protection: Continue locked brace for ambulation
	• Weight bearing: As tolerated (continue with crutches 3 to 4 weeks postop)
	• Passive Range of Motion: Self-ROM stretching (6 to 8 times daily)
	• Exercises:
	  • Muscle stimulation to quadriceps exercises
	  • Isometric quadriceps sets
	  • Straight Leg raises (4 planes)
	  • Leg Press (0° to 60°)
	  • Knee extension 90° to 40°
	  • Half squats (0° to 40°)
	  • Weight shifts
	  • Front and side lunges
	  • Uni-cam bicycle (low intensity cycling)
	  • Proprioception training
	  • Passive range of motion from 0° to 90°
	  • Patellar mobilization
	  • Well leg exercises
	  • Progressive resistance extension program—start with 1 lb., progress 1 lb. per week
	• Proprioception/Neuromuscular Training
	  • OKC passive/active joint repositioning 90°, 60°, 30°
	  • CKC joint repositioning during squats/lunges
	• Swelling control: Ice, compression, elevation
		• Protection: Maintain locked brace (some patients use ROM brace for ambulation)
		• Passive Range of Motion: Continue range of motion stretching and overpressure into extension (ROM should be 10° to 110°)
		• Exercises:
		  • Continue all exercises as in week two
		  • Passive Range of Motion 0° to 105°
		  • Bicycle for range of motion stimulus and endurance (emphasize ROM on bike)
		  • Pool walking program (if incision is closed)
		  • Eccentric quadriceps program 40 to 100 (isotonic only)
		  • Lateral lunges (straight plane)
		  • Front Step Downs
		  • Lateral Step-Overs (cones)
		  • Progress Proprioception drills, neuromuscular control drills
		  • Frequent bouts of ROM exercises

TIMELINE 35-2 Postoperative Rehabilitation After Posterolateral Corner Repair or Reconstruction (Continued)

PHASE III (Progressive Strengthening, weeks 4 to 10)

Weeks 4 to 5

- Protection: No immobilizer or brace, may use knee sleeve to control swelling/support
- Range of Motion
  - Self-ROM (four to five times daily using the other leg to provide ROM), emphasis on maintaining 0° passive extension
  - PROM 10° to 105° at 4 weeks
- KT 2000 Test: 20 lb. anterior and posterior test)
- Exercises:
  - Progress isometric strengthening program
  - Leg press (0° to 100°)
  - Knee extension 90° to 40°
  - Hip abduction and adduction
  - Hip flexion and extension
  - Lateral step-overs
  - Lateral lunges (straight plane and multi-plane drills)
  - Lateral step-ups
  - Front step-downs
  - Wall squats
  - Vertical squats
  - Standing toe calf raises
  - Seated toe calf raises
  - Biodex Stability System (Balance, Squats, etc.)
  - Proprioception Drills
  - Bicycle
  - Pool Program (Backward Running, Hip and Leg Exercises)
- Proprioception/Neuromuscular Drills
  - Tilt board squats (perturbation)
  - Passive/active reposition OKC
  - CKC repositioning on tilt board with sports RAC
  - CKC lunges with sports RAC

Weeks 6 to 7

- Protection: No immobilizer or brace, may use knee sleeve to control swelling/support
- Range of Motion
  - Self-ROM (four to five times daily using the other leg to provide ROM), emphasis on maintaining 0° passive extension
  - PROM 10° to 105° at 4 weeks
- KT 2000 Test: 20 and 30 lb. anterior and posterior test
- Exercises:
  - Continue all exercises from Weeks 4 to 5
  - Pool running (forward) and agility drills
  - Balance on tilt boards
  - Progress to balance and ball throws
  - Wall slides/squats
  - PROM 0° to 125°

Weeks 8 to 9

- Protection: No immobilizer or brace, may use knee sleeve to control swelling/support
- Range of Motion
  - Self-ROM (four to five times daily using the other leg to provide ROM), emphasis on maintaining 0° passive extension
  - PROM 10° 105 ° at 4 weeks
- KT 2000 Test: 20 and 30 lb. anterior and posterior test
- Exercises:
  - Continue all exercises from Weeks 4-7
  - Leg press sets (single leg) 0° to 100° and 40° to 100°
  - Wall squats
  - Perturbation training
  - Walking program
  - Bicycle for endurance
  - Biodex stability system
  - PROM 0° to 135°

FIGURE 35-7. Commercial vasopneumatic compression device used after surgery to decrease pain and swelling.

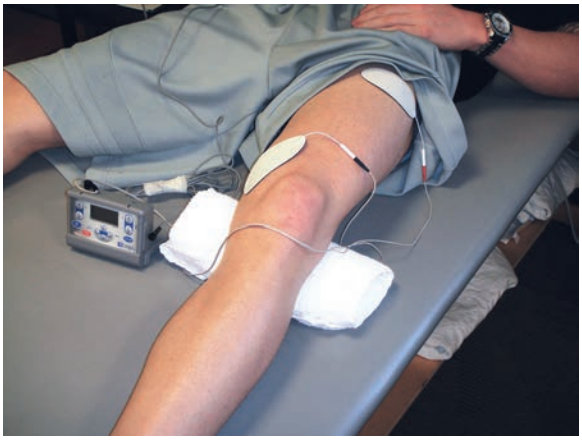

FIGURE 35-8. Neuromuscular electrical stimulation to the quadriceps musculature to improve muscle activation during straight leg raises.

- Also, gentle manual passive range of motion of the knee may be initiated to neuromodulate pain and aid in collagen alignment of the healing ligamentous tissue.
- PROM is allowed to 90° for the first 2 weeks.

Soft Tissue Techniques

- Scar mobilizations may be performed once the sutures are removed and adequate tissue healing has occurred.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Gentle calf and hamstring stretching may be performed to aid in maintaining full knee extension.

Other Therapeutic Exercises

- Neuromuscular electrical stimulation (NMES) (Figure 35-8) to the quadriceps are initiated immediately while performing straight leg raises during active flexion, abduction, and adduction. The patient may progress resistance ankle weights as strength returns and the patient displays good quadriceps control.
- Limited weight-bearing activities may be incorporated as a weight shift to improve neuromuscular control but

TIMELINE 35-2 Postoperative Rehabilitation After Posterolateral Corner Repair or Reconstruction (Continued)

Week 10	PHASE IV (Advanced Activity, weeks 10 to 16)		PHASE V (Return to Activity Weeks 16 and Beyond)
	Weeks 10 to 13	Weeks 14 to 16	

• KT 2000 Test: 20 and 30 lb. anterior and posterior test
• Isokinetic test: Concentric knee extension/flexion at 180 and 300/second
• Exercises:
  • Continue all exercises from Weeks 6 to 9
  • Continue stretching drills
  • Progress strengthening exercises and neuromuscular training
	• Exercises:
	  • May initiate running program week 12 if good quad control and ROM
	  • May initiate light sport program (golf)
	  • Continue all strengthening drills
	  • Leg press
	  • Wall squats
	  • Hip abd/adduction
	  • Hip flex/ext
	  • Knee extension 90° to 40°
	  • Hamstring curls (initiate at week 12)
	  • Standing toe calf
	  • Seated toe calf
	  • Step down
	  • Lateral step ups
	  • Lateral lunges
	  • Neuromuscular training
	  • Lateral step-overs cones
	  • Lateral lunges
	  • Tilt board drills
		• Progress program
		• Continue all drills above
		• May initiate lateral agility drills
		• Backward running
			• KT 2000, Isokinetic, and functional Tests before return
			• Exercises:
			  • Continue strengthening exercises
			  • Continue neuromuscular control drills
			  • Progress running and agility program
			  • Progress sport-specific training
			  • Running/cutting/agility drills
			  • Gradual return to sport drills
			6-Month Follow to up
			• Isokinetic test
			• KT 2000 test
			• Functional test
			12-Month Follow to up
			• Isokinetic test
			• KT 2000 test
			• Functional test

still need to monitor forces along the lateral and posterior knee.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Quadriceps, hip abductors, adductors, extensors, calf, peroneals

Sensorimotor Exercises

- Weight shifting onto a stable surface may be initiated immediately then progressed to a weight shift onto a foam surface to further challenge the neuromuscular control system.

Open and Closed Kinetic Chain Exercises

- See above.

Techniques to Increase Muscle Strength, Power, and Endurance

- At this phase, activation of the quadriceps is the primary principle through the use of NMES.

Neuromuscular Dynamic Stability Exercises

- The patient may begin controlled balance activities beginning with a weight shift onto the involved extremity and progressing to a weight shift onto a foam or unstable surface.

Functional Exercises

- At this stage, the patient is instructed to ambulate in the Dynasplint locked at 0° while using axillary crutches. A lateral heel wedge may be utilized for a genu varum knee to decrease stress through the lateral joint line and open up the medial joint line to decrease contact stress forces.

Milestones for Progression to the Next Phase

- Full passive knee extension
- Good quadriceps control with SLR and quad set
- Good patellar mobility
- Minimal joint effusion
- Flexion PROM to 90°
- Independent ambulation in crutches

Phase II: Earl Rehabilitation (weeks 2 to 3 postoperatively)

Goals

- Progress to independent ambulation without crutches
- Initiate weight-bearing strengthening exercises

- Improve quadriceps strength to ≥ 60% of contralateral side
- Discharge Dynasplint brace at 6 weeks postoperative
- Gradual increase to full passive knee extension
- Gradually increase knee flexion
- Diminish swelling and pain
- Muscle control and activation
- Restore proprioception/neuromuscular control
- Normalize patellar mobility

Clinical Pearl

Progress to full PROM over the first 6 weeks following the surgery. The rehabilitation specialist should continue to protect the healing structures through progressive weight-bearing activities and the Dynasplint brace.

Protection

- Crutches may be discontinued by 3 weeks postoperatively as long as the patient displays good quadriceps control and feels confident about the extremity.

Management of Pain and Swelling

- Moist heat, cryotherapy, and vasopneumatic compression devices may be utilized to control pain and inflammation. Typically, the patient is weaning off of the narcotic pain medications and has begun utilizing nonsteroidal antiinflammatory (NSAIDs) medication.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Patellar mobilizations may be performed as needed. Manual PROM of the tibiofemoral joint is progressed to >125° by the end of this phase.

Soft Tissue Techniques

- Cross-friction massage may be utilized to break up adhesions at the incision sites.
- Soft tissue mobilization techniques may be used to decrease muscular tone of the quadriceps and hamstrings if this restricts the patient's ability to achieve flexion and extension PROM.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Gentle gastrocnemius and soleus towel stretching may be performed with special care to avoid hamstring stretching.

Other Therapeutic Exercises

- Continue with a progressive resistance exercises program including SLRs, Leg Press (0° to 60°), minisquat (0° to 40°), and step downs to improve quadriceps control.

FIGURE 35-9. Single leg stance on foam to further challenge the patient's dynamic stability.

- Total ankle strengthening may be incorporated using resistance bands in all four directions to maintain strength before advancing balance drills.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Quadriceps
- Hip abductors, adductors, extensors, external rotators
- Gastroc-soleus complex
- Core stabilization

Sensorimotor Exercises

- Balance onto unstable surfaces

Open and Closed Kinetic Chain Exercises

- Bicycle (depending on ROM)
- Continue resisted SLRs with NMES
- Leg Press (0° to 60°)
- Multi-hip (abduction, abduction, extension, flexion)
- Clams
- Seated hip ER/IR
- Sidelying planks with hip abduction 30-second hold
- Prone planks with hip extension 30-second hold

Techniques to Increase Muscle Strength, Power, and Endurance

- See above

Neuromuscular Dynamic Stability Exercises

- Single leg stance on unstable surface (Figure 35-9)
- Gentle perturbation training

Functional Exercises

- Progressive gait training
- Normalize gait
- Eccentric quadriceps control on step-downs

Milestones for Progression to the Next Phase

- Active ROM 0° to 115°
- Quadriceps strength 60% > contralateral side (isometric test at 60° knee flexion)
- Unchanged KT Test bilateral values (+1 or less)
- Minimal to no full joint effusion
- No joint line or patellofemoral pain

Phase III: Progressive Strengthening (weeks 4 to 10 postoperatively)

Goals

- Minimal to no joint effusion
- PROM 0° to 110°
- Minimal pain
- No joint line pain
- Restore full knee range of motion (0° to 125°)
- Improve lower extremity strength
- Enhance proprioception, balance, and neuromuscular control
- Improve muscular endurance
- Restore limb confidence and function

Clinical Pearl

The patient will restore full PROM without pain in this stage and progressive strengthening of the entire lower extremity. If full ROM is not attained, low load long duration stretching should be utilized to slowly stretch out the scar tissue (collagen), which will help to regain the lost motion.

Protection

The patient progresses from the Dynasplint to a knee sleeve or hinged knee brace while walking because of the continued weakness of the lower leg musculature.

Management of Pain and Swelling

- The patient may take NSAIDs as needed to control the mild pain and inflammation that may persist.
- A compression sleeve may be utilized to control or minimize knee joint effusion as the patient's activity level increases.

Techniques for Progressive Increase in Range of Motion

Manual Therapy and Soft Tissue Techniques

- The rehabilitation specialist should continue to mobilize the patella, and progress knee flexion and extension ROM.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Quadriceps and hamstring static stretching may be initiated to improve overall flexibility.

Other Therapeutic Exercises

- Leg press
- Lateral lunge (straight plane)
- Lateral step-down
- Front step-down
- Multi-axis hip (four directions)
- Lunges
- Wall squat
- Proprioception drills on a Biodex stability system

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Quadriceps
- Total hip musculature
- Gastrocnemius
- Core stabilization

Sensorimotor Exercises

- Balance onto unstable surfaces
- Dynamic stabilization drills
- Neuromuscular control drills

Open and Closed Kinetic Chain Exercises

- See above

Techniques to Increase Muscle Strength, Power, and Endurance

The patient is instructed to progress resistance for each exercise along with working on timed bouts to improve endurance. Cardiovascular exercises including cycling, elliptical training, and swimming may be utilized as well.

Neuromuscular Dynamic Stability Exercises

- Tilt board squats
- Single leg balance onto unstable surfaces
- Perturbation training while on unstable surfaces (Figure 35-10)

Functional Exercises

- Progressive walking program

Milestones for Progression to the Next Phase

- Full PROM
- Satisfactory clinical examination
- >4/5 MMT throughout LE
- AROM 0 to 125° or greater
- Quad strength 75% of contralateral side, knee extension flexor:extensor ratio 70% to 75%
- No change in KT values (comparable with contralateral side, within 2 mm)
- No pain or effusion

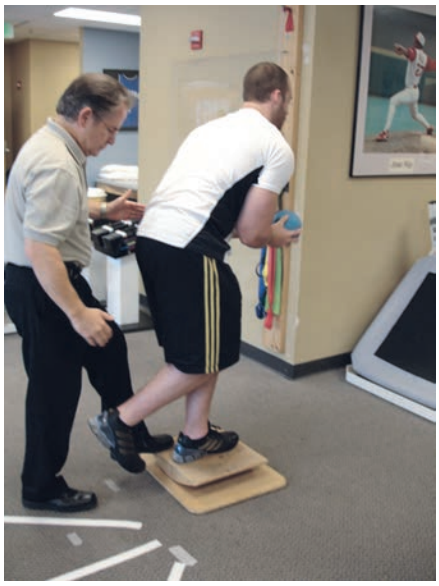

FIGURE 35-10. Perturbation training on a tilt board to enhance dynamic stability and neuromuscular control.

- Satisfactory clinical exam
- Satisfactory isokinetic test (values at 180°)
  - Quadriceps bilateral comparison 75%
  - Hamstrings equal bilateral
  - Quadriceps peak torque/body weight 65% at 180°/s (males) and 55% at 180°/s (females)
  - Hamstrings/quadriceps ratio 66% to 75%
- Hop Test (80% of contralateral leg)
- Subjective knee scoring (modified Noyes System) 80 points or better

Phase IV: Advanced Activity (weeks 10 to 16 postoperatively)

Goals

- Normalize lower extremity strength
- Enhance power and endurance
- Improve neuromuscular control
- Initiate sports-specific drills

Clinical Pearls

It is imperative that the patient continues to improve strength, power, and endurance while maintaining knee homeostasis. The rehabilitation specialist may want to consider an unloader brace to decrease medial knee joint forces. A lateral heel wedge or custom orthotic in the patient's shoe may be used to control varus loading in the knee joint, as well. Sports-specific drills may be initiated toward the end of this phase including a running program that slowly progresses straight-line running distances.

Management of Pain and Swelling

- NSAIDs as needed
- The patient may continue to wear a compression sleeve with daily activities and should ice after activities

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Complete lower extremity stretching may be performed. Consideration for dynamic stretching may be performed before exercises while the athlete may perform a static stretching program after exercising.
- Manual soft tissue may be performed as needed to address limitations or delayed onset muscle soreness after exercise progression.

Other Therapeutic Exercises

- Total leg strengthening may be performed to enhance strength, power and endurance.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- At this stage, the athlete may continue to progress quadriceps and hip strengthening. Hamstring strengthening should be initiated; however, the rehabilitation specialist should continue to monitor for posterolateral knee pain.

Sensorimotor Exercises

- Balance activities are progressed to include more dynamic movements to simulate the athlete's sport. Perturbation training may be used to create a postural disturbance upon the patient to further challenge dynamic stability and neuromuscular control.

Open and Closed Kinetic Chain Exercises

- Total lower body and core strengthening emphasizing dynamic movements and single leg isolation activities
  - Leg Press (0° to 100°)
  - Multi-axis hip
  - Initiate isolated hamstring strengthening at 8 weeks postoperative
  - Step downs
  - Forward and lateral lunges
  - Forward and lateral step downs
  - Sidelying clams
  - Hip ER/IR
  - Bridging
  - Plank with hip abduction and extension
  - Sport cord resistance movements

Techniques to Increase Muscle Strength, Power, and Endurance

- See above.

Neuromuscular Dynamic Stability Exercises

- See above.

FIGURE 35-11. Antigravity treadmill used to decrease stress on the knee joint while allowing the patient to progress through a running program.

Plyometrics

- Plyometrics may be initiated on the leg press utilizing half of the patient's body weight as an initial starting point.
- Progression to box jumps may begin if the patient displays good quadriceps control and no pain.

Functional Exercises

- The patient may initiate a running program in a pool or antigravity treadmill (Figure 35-11) as symptoms allow.
- Lateral movement drills may be incorporated if the patient displays adequate dynamic stability and neuromuscular control.

Milestones for Progression to the Next Phase

- Full ROM
- Unchanged KT 2000 Test (within 2.5 mm of opposite side)
- Isokinetic test that fulfills criteria
- Quadriceps bilateral comparison (80% or greater)
- Hamstring bilateral comparison (110% or greater)
- Quadriceps torque/body weight ratio (55% or greater)
- Acceleration rate at 0.2 seconds (80% of quads peak torque)
- Hamstrings/quadriceps ratio (70% or greater)
- Proprioceptive test (100% of contralateral leg)
- Functional test (85% or greater of contralateral side)
- Satisfactory clinical exam
- Subjective knee scoring (modified Noyes System) (90 points or better)

Phase V: Return to Activity (weeks 16 to 22 postoperatively)

Goals

- Full ROM
- Pain free
- No effusion present
- Isokinetic testing:
  - Bilateral quadriceps comparison within 85%
  - Bilateral hamstrings within 110%
  - Hamstrings/quadriceps ratio within 70%
  - Quadriceps torque: body weight ratio ≥ 65%
- Satisfactory clinical examination
- Gradual return to full-unrestricted sports
- Achieve maximal strength and endurance
- Normalize neuromuscular control
- Progress skill training

Clinical Pearl

In this phase, the patient gradually returns to full, unrestricted sports activities while continually building upon the previous exercises that focus on strength, power, and endurance.

Management of Pain and Swelling

- As needed. See above.

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Dynamic stretching may be utilized before activities followed by a comprehensive static stretching program once activities have been completed.

Other Therapeutic Exercises

- At this point, a total body strengthening program and core stability program is progressed to further challenge the patient's dynamic stability and neuromuscular control.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Quadriceps
- Hamstrings
- Hip musculature
- Calf musculature
- Core stabilizers

Sensorimotor Exercises

- Biodex Stability System (balance, squats, etc.)

Open and Closed Kinetic Chain Exercises

- Leg press (0° to 100°)
- Knee extension 90° to 40°

- Hip abduction and adduction
- Hip flexion and extension
- Lateral step-overs
- Lateral lunges (straight plane and multi-plane drills)
- Lateral step-ups
- Front step-downs
- Hamstring-Romanian dead lifts (RDLs)
- Wall squats
- Vertical squats
- Standing toe calf raises
- Seated toe calf raises

Plyometrics

- Box jumps
  - Double legged
  - Single legged
  - Two boxes
  - Jump roping
  - Sport cord lateral hop onto foam with ball toss

Functional Exercises

- Interval running program beginning with straight line and progressing to a cutting program at predetermined intervals
- Plyometrics
- Sport-specific drills depending on the patient's sport, position, and demands

Sport-Specific Exercises

- Lateral cariocas
- Figure 8s
- Shuttle runs
- Interval sprinting program
- Specific sport drills and activities

Milestones for Progression to the Next Phase

- See below

Criteria for Return to Sport

General

- Full ROM
- Pain free
- Isokinetic testing:
  - Quadriceps torque to body weight ratio ≥ 65%
  - Hamstrings/quadriceps ratio within 70%
  - Bilateral comparison of quadriceps within 90%
  - Bilateral hamstrings within 100%
  - Acceleration rate at 0.2 seconds (80% of quads peak torque)
- Satisfactory clinical examination
- Completion of sport-specific program
- Clearance by MD

Sport-Specific

- A running program that involved starting and stopping on command may be used to determine return to play
- Lateral shuffles, cariocas, and timed shuttle runs can determine lateral function and cutting abilities.

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Continue with total body strengthening and stretching program
- Aerobic conditioning program
  - Biking
  - Swimming
  - Elliptical training
  - Interval sprinting

Exercises and Other Techniques for Prevention of Recurrent Injury

- Plyometric jumping working on landing techniques
- Hip abductor/extensor/external rotation strengthening
- Perturbation training to further enhance dynamic stability and neuromuscular control

Evidence

Geeslin AG, LaPrade RF: Outcomes of treatment of acute Grade-III isolated and combined posterolateral knee injuries. *J Bone Joint Surg Am* 93:1672–1683, 2011.

This prospective study analyzed the outcomes of 29 grade III posterolateral knee injuries treated with an anatomic repair or reconstruction within 6 weeks of injury. At an average of 2.4 years following treatment, the mean IKDC and Cincinnati Knee Rating scores improved significantly along with lateral compartment gapping as determined by varus stress radiographs. (Level IV evidence)

LaPrade RF, Wentorf FA, Fritts H, et al: A prospective magnetic resonance imaging study of the posterolateral and multiple ligament injuries in acute knee injuries presenting with a hemarthrosis. *Arthroscopy* 23:1341–1347, 2007.

This prospective MRI study evaluated 331 consecutive acute (within 30 days) knee injuries with a hemarthrosis at a large, metropolitan imaging facility with six sites. The incidence of a posterolateral knee injury with an acute hemarthrosis was 9.1%. The authors also determined that most PCL and posterolateral corner injuries occur in combination with other ligament injuries. (Level IV evidence)

LaPrade RF, Johansen S, Engebretsen L: Outcomes of an anatomic posterolateral knee reconstruction: surgical technique. *J Bone J Surg Am* 93(Suppl 1):10–20, 2011.

This study aimed to document the clinical stability and functional outcomes on posterolateral reconstruction surgery. This two-center study looked at 64 patients with chronic grade 3 posterolateral instability. A significant improvement was noted on the IKDC scores for varus opening at 20°, external rotation at 30°, reverse pivot shift, and single leg hop at an average of 4.3 years from surgery. (Level III evidence)

Stannard JP, Brow SL, Farris SL, et al: The posterolateral corner of the knee: Repair versus reconstruction. *Am J Sports Med* 33:881–888, 2005.

This cohort study evaluated the repair (n = 39) versus reconstruction (n = 25) of acute posterolateral corner injuries in 63 patients with 64 injuries. The authors showed that the repaired knee showed inferior results on laxity and failure rates. They went on to recommend the use of a reconstruction rather than a primary repair in patients who sustain a posterolateral corner tear. (Level II cohort study)

Multiple-Choice Questions

QUESTION 1. During Phase I of rehab of a PLC injury, it is imperative to:

A. Obtain full knee flexion immediately
B. Maintain non–weight-bearing status for the first 3 weeks to limited stress to the healing tissues
C. Obtain full knee extension, while limiting hyperextension
D. Ice the knee for 20 minutes every hour throughout the first 2 weeks with the knee flexed to avoid overstressing the tissues

QUESTION 2. Progression from the Dynasplint to a knee sleeve or hinged brace occurs in which phase of rehab?

A. At the end of Phase I (week 2)
B. Mid Phase II (around week 4)
C. Phase III (6 to 10 weeks)
D. Beginning of Phase V (14 weeks)

QUESTION 3. Criteria for return to sport include all of the following except:

A. Bilateral quadriceps strength within 90% on isokinetic testing
B. Pain free, full ROM
C. Completion of sport-specific program
D. Hamstring/quadriceps ratio within 100%

QUESTION 4. This should be avoided for 8 weeks of therapy in rehab for a PLC injury:

A. Active hamstring activity
B. Active quadriceps activity
C. Active gastrocnemius activity
D. All of the above

QUESTION 5. If full PROM has not been restored during Phase III of rehab, this can be used to regain the lost motion:

A. Quick thrust grade V manipulations of the tibiofemoral joint
B. Low-load long-duration stretching
C. Continued strengthening of the primary muscles surrounding the joint will help regain the lost ROM
D. None of the above, if full ROM has not been restored by this point it is unable to be restored

QUESTION 6. All of these are activities the patient should be doing in Phase III (weeks 6 to 10) except:

A. Single leg balance on unstable surfaces with perturbation training
B. Plyometric exercises
C. Progressive walking program
D. Multi-hip machine in four directions (abduction, adduction, extension, flexion)

Answer Key

QUESTION 1. Correct answer: **C** (see Phase I Clinical Pearl)

QUESTION 2. Correct answer: **C** (see Phase III Protection)

QUESTION 3. Correct answer: **D** (see Criteria for Return to Sport)

QUESTION 4. Correct answer: **A** (see Phase I Clinical Pearl)

QUESTION 5. Correct answer: **B** (see Phase III Clinical Pearl)

QUESTION 6. Correct answer: **B** (see Phase III)

BEYOND BASIC REHABILITATION: RETURN TO RUGBY LEAGUE AFTER POSTEROLATERAL CORNER KNEE RECONSTRUCTION WITH AUTOGRAFT

John Maguire, MBBS, FRACS, MSM, FAOA, and Steven Sartori, B Physio, FPCP

ASPECTS OF RUGBY LEAGUE THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- High-grade, posterolateral corner (PLC) knee injury requiring autograft reconstruction is a rare injury in rugby league. It is a challenging problem for medical staff to return players to rugby league at an elite level, particularly if there is a concurrent anterior cruciate ligament (ACL)/PCL injury, or high-grade articular cartilage injury.
- Surgical stabilization and high-level active knee control are required to avoid knee varus and extension stress during pivoting and cutting maneuvers. These are inherent in most football codes, not to mention direct contact injuries.
- Rugby league is a contact sport played mainly in Australia, New Zealand, Pacific Islands, France, and throughout the United Kingdom. It is a multidirectional ball running game requiring power, agility, speed, repeat high intensity sprinting, and endurance. The game duration is 80 minutes, with 40 minute halves, and little stoppage time.
- There are limited player interchanges so player endurance is paramount especially in key positions such as halfback, fullback and hooker. There are often multiple players engaged in the tackle. The tackle involves contact, including wrestling and grappling. An individual player may make up to 60 tackles per game.
- No hard bracing or helmets are allowed thus limiting the use of knee bracing. Some soft bracing, padded headgear, and taping is allowed.
- Rugby league has a high overall rate injury rate, averaging between 60 and 80 injuries per 1000 player hours. Up to 75% of an elite club's senior roster of 35 players will sustain at least one injury per season, which will result in missed game time during the season.
- Each team on average will have six players unavailable for first grade games every week. Knee injuries account for 15.3% of total injuries.
- The most common mechanism of knee injury in elite rugby league occurs during tackling, in particular when being tackled.[1]
- In 2012, the National Rugby League Injury Surveillance reported a total of 16 ACL injuries throughout the 16 national clubs. This accounted for 20.5% of total knee injuries reported and resulted in 259 missed games in total.[2]
- PCL injuries for 2012 totaled 7, accounting for 9.0% of total knee injuries resulting in only 29 missed games.
- There were no isolated PLC, or combined PLC/cruciate injuries reported in the National Rugby League (NRL) 2012 injury surveillance report.[2]
- As with other high-speed contact pivoting sports, returning from PLC injury, in this case specifically PLC auto graft reconstruction, is only possible with excellent surgical planning and technique.
- Close communication between physical therapist/athletic trainer and surgeon are required. Excellent training routines and sensible return to sport considerations are required. Particular attention to all aspects of strength, power, neuromuscular, agility, reactive, and speed training is necessary, and involves constant monitoring and feedback to the athlete to avoid knee varus and extension stress to the graft.

Introduction

Literature

- This is a rare injury, with little or no data relating to return to competition in all football codes in Australia, at the elite professional level.
- With an increasing body of evidence emphasizing neuromuscular knee control in injury prevention and rehabilitation[3-5] and with feedback to the athlete being instantaneously available with the use of video, force plates, and muscle stiffness testing, there is an evidence based approach to rehabilitation which is functionally based, rather than time based, and provides extra objective insight to inform clinical decision-making processes.
- Traditional strength testing, including either isokinetic (if available) or other strength indices, accepted neuromuscular testing (e.g., hop tests) and field-based agility testing are still utilized and are required to help clinical decision-making regarding safe return to sport.

Advanced Rehabilitation Program

- There are other monitoring variables which can contribute to clinical decision making. These can include subjective well-being data (e.g., knee pain rating/10) and objective maximum voluntary contraction (MVC) dynamometry. These are recorded daily, and may assist

in session planning for the next day, or week, in an attempt to avoid over-training, or concurrent soft tissue injury especially in the later stages of intense sport specific training.
- Adductor MVC testing (squeeze test) has been shown to be reliable and predictive of groin pain in elite level Australian Rules football players.[6,7] MVC testing can also be carried out on other muscle groups and may give a daily indication of whether progression is safe.
- As can be seen there are many things to consider before a return to sport following this severe and challenging injury. The following protocols will demonstrate what we do with our players at an elite level in Rugby League in Australia.

Phase I: Advanced Strength and Conditioning Programs

- The commencement of advanced strength and conditioning is in the late stage of rehabilitation from 6 months.
- The following text is written with the assumption that the athlete has successfully completed the previous rehabilitation milestones as listed in the Rehabilitation Timeline, specifically that there has been demonstrated objective advanced proprioceptive control (e.g., star excursion test/Y balance test), single leg hop with positional knee control, normal running biomechanics (video assessment), and minimal joint effusion post exercise.
- A time-frame-based rehabilitation protocol without functional milestones, especially neuromuscular and strength markers, is not recommended. This has been shown to be associated with increased reinjury risk.[8,9] It should also be mentioned that early consideration of combined injury also needs to be taken into account well before the athlete enters the advanced phases of rehabilitation. Rehabilitation for an isolated PLC reconstruction will differ from a combined ACL/PLC injury, or combined PCL/PLC injury. Other concomitant procedures such as tibial osteotomy and articular cartilage repair/restorative procedures will also change some parameters of rehabilitation, and may also influence the decision of whether the athlete will be able to return to their preinjury level of sport, or even return to sport at all.
- For example, return to play rates in National Football League (NFL) after ACL reconstruction have been shown to be lower than previously perceived with 63% of NFL athletes returning to NFL game play.[10]
- Return to play rates in elite rugby league are similar to this figure at 66% (authors' own data). Combined cruciate/PLC reconstruction return to play rates at elite level are not well- known.
- The primary influences of rehabilitation for these procedures in the early phases are dictated by biological tissue healing times and involve weight-bearing status, range of motion (ROM) parameters, open kinetic chain (OKC) restrictions, and bracing use. Many of these parameters are variable depending on the surgeon's instructions, and the procedures performed.
- There is a paucity of high level evidence base for many rehabilitation parameters, however there is a growing evidence base for the use of OKC knee extension in ACL rehabilitation after 12 weeks postoperatively between 90° and 60° ROM without demonstrated graft stress/joint laxity.[11-15]
- This in particular influences a combined ACL/PLC injury since OKC knee extension can be initiated relatively early, and assist in quadriceps strengthening compared to CKC exercises alone.[11,13,15] OKC knee extension for combined ACL/PLC injuries should therefore be limited to 90° to 60° until late stage rehabilitation; however, the optimal time to resume full range OKC extension remains unclear.[14,15] OKC knee extension for combined PCL/PLC injuries should be limited to 0° to 60°,[15,16] and combined ACL/PCL/PLC should be limited to 60° to 30°.[15,16]
- Isolated PLC and PCL/PLC combined injuries have not traditionally used OKC knee flexion until later stage rehabilitation for similar fears of graft stress/joint laxity incurred,[4,17] however, there needs to be further quality research to quantify this, as has been performed with ACL rehabilitation.
- Similarly, bracing and weight-bearing parameters need to be further investigated in relation to PLC injury and combined cruciate/PLC injury in relation to graft stress and induced joint laxity.
- Traditionally rehabilitation following lateral side ligament repair is more conservative than following ACL reconstruction, however Kinzer et al. demonstrated excellent outcomes following ACL/lateral side knee reconstruction utilizing contralateral patella tendon graft with their Knee Symmetry Model, not involving the use of postoperative bracing, or limiting either ROM or weight-bearing status.[8]
- Until a wider level evidence base is established, then rehabilitation limitations for combined PCL/PLC and isolated PLC injuries should remain conservative.

Periodization

- Advanced strength and conditioning programs can include an initial continued linear periodization program from the previous rehabilitation phase where training load is primarily concerned with progressive muscle hypertrophy and endurance (high volume/low intensity), rather than aspects of power and strength.
- Progression to an undulating/nonlinear periodization once there is an adequate strength base will allow recovery periods between more intense strength training periods, variation to reduce training adaptation plateau, and allow changes in velocity and resistance to pursue power and strength emphasis without compromising technique.[18]
- Undulating/nonlinear programs have been shown to increase strength and motor performance in healthy, young trained athletes. There is little literature available on injured athletes.[18,19]
- A short duration linear periodization could also be used, however, it would have to progress into a strength/power phase to be appropriate.[19] There is subjective evidence that a nonlinear periodization program is

beneficial in most rehabilitation phases because they will offer the ability to train more than one parameter (e.g., hypertrophy, strength, endurance, power) at a time, while still emphasizing one of them in a particular phase.[19]

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- CKC exercises have been traditionally preferred in rehabilitation due to their demonstrated ability to produce quadriceps and hamstring group cocontraction, increase joint proprioception, and increase joint compression,[5,15] however, there is evidence demonstrating increased tibial translation and graft stress at angles greater than 60 degrees.[4,5,13,15,17]
- CKC quadriceps exercises should therefore be limited to those parameters in all combined and isolated PLC injuries until at least 4 months postoperatively.[4,17]
- CKC hamstring exercises in mid stance and terminal stance positions, with progression to eccentric control are important in later stage rehabilitation to control unwanted thrust into knee hyperextension.[4]
- Evidence supporting the implementation of strength and conditioning principles into specific late stage athletic rehabilitation programs is lacking. General consensus includes the progression from high volume/low intensity hypertrophy and endurance training into a strength/power phase, and eventually a specific power phase depending on the sports requirements.[19]
- Similar recommendations are made with regard to conditioning programs tailoring the explosive speed/endurance/repeat high intensity sprinting ability, and the energy system requirements of the sport.[19]
- Specific game performance requirements can be measured using global positioning system (GPS) and heart rate data and are integrated into late-stage training prescription to simulate game-specific loading.[20] For example, GPS data indicate that rugby league players will perform one bout of repeated high intensity loading every 5 minutes on average, but may be as high as every 2 to 3 minutes. One repeated high intensity effort bout will consist of 7 to 13 efforts (sprints/contacts/wrestle), with efforts lasting 7 to 8 seconds. Recovery between efforts can be as short as 5 seconds.[20] Conditioning training in late phase rehabilitation will require high-intensity repeat bouts of exercise with little recovery to physically and mentally prepare

TIMELINE 35-3: **Return to Rugby League after PLC Autograft Reconstruction (Isolated)**

Phase I: PRELIMINARY POSTOPERATIVE REHABILITATION (weeks 0 to 16 postoperatively)

Weeks 1 to 2

- Touch Weight Bearing (TWB) independent transfers/mobility
- Pain control
- Edema control: cryotherapy, elevation, compression
- Quadriceps setting/straight leg raises (SLR) in brace locked in full extension
- Quadriceps E-stimulation
- Ankle pumps
- Passive range of motion (PROM) and active assisted range of motion (AAROM) exercises aiming for 90° knee flexion/0° extension by end of week two
- Manual patella-femoral mobilizations
- Core (lumbo-pelvic and hip) stabilization exercises

Weeks 3 to 6

- PWB to full WB as tolerated (use pain as a guide)
- PROM/AAROM exercises aiming for 120° knee flexion/full extension by end of Week 6
- Quadriceps setting/SLR with EMG biofeedback

Weeks 7 to 12

- Weight bearing as tolerated
- Gait retraining, remaining PWB until normal gait pattern/SLR without extension lag
- Discontinue brace once normal gait pattern
- Progressive quadriceps resistance using TheraBand or weights as appropriate
- Stationary bike (submaximal once ROM achieved)
- Swimming: no fins/kick/flip turn/breaststroke
- Co-contraction of quadriceps/hamstrings in weight bearing with EMG biofeedback
- Centre of gravity (COG) weight shift/low level balance-proprioception
- Manual therapy: soft tissue techniques/joint mobilization as appropriate
- Single leg stance exercises
- Progress core exercises and hip stabilization

Weeks 13 to 16

- FWB normal gait pattern/No virus thrust
- Closed kinetic chain (CKC) leg press to a maximum of 70 feet flexion
- OKC knee extension 90° to 60° with ACL involvement/90–0° with PCL/sagittal plane only with MCL, FCL, or PLC involvement
- No OKC resisted knee flexion
- Eccentric/concentric hamstring CKC (e.g., bridging)
- CKC squat rack/squat machine not exceeding 70′ feet flexion
- CKC progression including single leg stance/resistance
- Resistance stationary cycle
- Swimming no flip turns
- Elliptical machine (submaximal)
- Stretching of tight musculotendinous/neural structures as appropriate (avoiding knee hyperextension/varus positioning)
- Progressive core/hip stabilization (floor-based core)
- Progressive balance/proprioceptive exercises from static to dynamic/add unstable base of support (BOS) (e.g., wobble board/BOSU step/squat)

the athlete for eventual return to that particular sport.

Olympic Lifts Used in the Training Program

- Submaximal Olympic lifting such as squatting (Figure 35-12), dead lifting, power clean, snatch and power press can be initiated in this phase, with initial emphasis on technique and knee alignment. Increased resistance loading can be progressively added once demonstrated correct technique is achieved. Verbal, mirror, and video feedback can be useful to assist in teaching correct technique.
- The objective is to increase training adaptation with velocity and resistance variables during this phase as a building block into the final power phases.[19] Higher load eccentric hamstring exercises (e.g., Nordic/Russian deadlift—Figure 35-13) should continue to be progressed to control unwanted knee extension forces.

Training Principles Used in the Design of the Program

- Program design during the final phases of rehabilitation will incorporate multiple training principles of progression, overload, variation, player position individualization, and game-specific demands.

FIGURE 35-12. Front squat—Olympic lift.

TIMELINE 35-3 Return to Rugby League after PLC Autograft Reconstruction (Isolated) (Continued)

PHASE II: ADVANCED STRENGTH AND CONDITIONING (weeks 16 to 24 postoperatively)	PHASE III: PERFORMANCE ENHANCEMENT (months 6 to 8 postoperatively)	PHASE IV: SPORT to SPECIFIC TRAINING (weeks 9 to 12 postoperatively)
• Progressive interval walking program including bodyweight supported walking (e.g., AlterG) • Resistance cycling including road cycling • Progressive CKC leg press/squat • Progressive OKC knee extension • Progressive CKC eccentric hamstring control (e.g., slide board bridge) • Commence OKC knee flexion/including PCL involvement • Commence weight-bearing eccentric hamstring exercises (Russian Dead Lift/no Nordic) • Progressive plyometric/agility exercises: supported jumping, jumping, bounding, hopping with feedback +/– video/neutral knee alignment/soft controlled landing into knee flexion avoiding knee extension/lumbo-pelvic control/trunk control • Advanced proprioceptive drills including hopping/landing onto unstable BOS • Advanced core/pelvic strengthening including limb movement/trunk rotation/single leg stance • Commence progressive interval running program including video feedback/gait analysis/bodyweight support running/once demonstrating single leg stance control with repeated squat • Continue swimming/alternate NWB conditioning on nonrunning days	• Advanced strengthening including progressive quadriceps/hamstring exercises, submax Olympic lifts, eccentric hamstring/gluteal exercises, OKC and CKC exercises (see Figures 35-10 to 35-13) • Progressive running including straight-line interval speed drills/repeat interval conditioning drills/endurance-distance running with demonstrated normal biomechanics • Advanced plyometric drills without pivoting/cutting (e.g., single leg hop/landing/bounding; see Figure 35-14) • Advanced core/lumbo-pelvic exercise • Advanced proprioceptive drills (e.g., hop and land with rotation onto BOSU) • Continued alternate low load conditioning on nonrunning days	• Sport specific strength exercises including Olympic lifts (e.g., squat, hang clean, clean press) • Maximal sprint drills/repeat interval sprinting • Agility drills including pivoting/cutting with demonstrated (video) neutral knee alignment and avoiding cutting in knee extension (e.g., W,Z,T pattern between poles; see Figure 35-15) • Repeated hop/jump/landing drills including rotational directions with abovementioned alignment (as per text) • Sport-specific conditioning and training drills (see Figure 35-16) • Contact/wrestle training once the abovementioned is demonstrated

FIGURE 35-13. Nordic high load eccentric hamstring exercise.

FIGURE 35-14. Weighted single leg squat—combined closed chain lower limb/trunk control/open chain shoulder/balance exercise.

- The final sport-specific phase of training will continue to adopt most of these principles, but will become more tailored to game-specific and positional demands. For example, the total distance and speed of running for an outside back during a game may be more than that of a forward/back row player, but the forward/back row player will have an increased number of collisions/tackles requiring more strength/power. This will alter the strength and conditioning program for individual players.

Application of Acute Training Variables

- Strength training typically involves a load of 80% to 100% of one maximal repetition (1RM), utilizing one to six repetitions with 3 to 5 minutes recovery. The calculation of 1RM for the rehabilitating athlete can be difficult, but most elite clubs will have this information preinjury, or can be calculated utilizing loading charts.[19]
- Power training requires a primary component of velocity of movement at a reduced load with longer recovery, utilizing one to six repetitions with resistance loads of 30% to 65% of 1RM. During the later stages, power training may be manipulated into shorter recovery periods, with higher load to simulate actual game loads.[18,19]
- Once there is an established strength base (e.g., squat 1.5 times body weight [see Figures 35-14 and 35-15]), plyometric training is progressed during this phase to enhance neuromuscular and power adaptations.[18] Progression from bilateral to single limb bounds, jumps and hops can occur with feedback regarding trunk, lumbopelvic, and knee positioning. Feedback may involve video, force plate/ground reaction force, or muscle stiffness/velocity measures.
- Training loads vary, however four to six sets of five to eight repetitions, with 30 to 90 seconds recovery time, two to four times per week is typically introduced.[21]

FIGURE 35-15. Weighted overhead squat—combined closed chain lower limb/trunk control/open chain shoulder exercise.

Total foot contacts per session can vary between 20 and 50,[18,21] but is typically symptom based.

- Safe timing of plyometric training (Figure 35-16) is important and can usually be done early in the training session before fatigue. Although plyometric training is critical to ensure neuromuscular adaptation, advanced proprioceptive exercises (not involving cutting/pivoting) should still continue in an attempt to minimize the risk of reinjury, or contralateral leg injury (Table 35-1).
- Through the more advanced phases of training, data monitoring, including MVC, pain rating, general soreness, and specific muscle tightness rating will assist in forward planning conditioning/agility/neuromuscular components of training. Noted changes may occur after increasingly heavy resistance training, and may

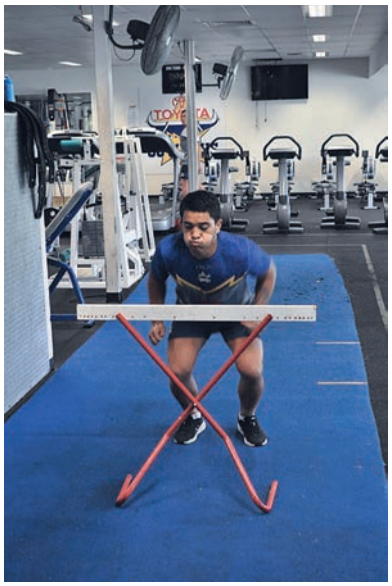

FIGURE 35-16. Plyometrics power jump-land.

Table 35-1 North Queensland Cowboys 2013 Weights Periodization Plan

Phase 1	Phase 2	Phase 3
Hypertrophy	Strength/power	(Specific)
Lower weights	Lower weights	Whole body
Front squats 5×8	Squats 5×4	Front squats 5×5
Zirchers 3×10	Deadlifts 1×5, 3×3	RDLs 3×6
Clean pulls (hang) 5×5	Three hurdles > prowler	Split squats 3×6
Reverse lunges 3×8	DB step-ups 3×6	Split jerks 4×5
One-leg DB RDLs 3×8	RDLs 3×6	Bench rows 3×8
Abs		Wted chins 3×10 > ABS

place other musculotendinous structures at risk of acute strain injury due to fatigue, or load-induced tendinopathy. Planning high-intensity running after heavy resistance training is not recommended, and should be performed on alternate days.

Phase II: Performance Enhancement Training Techniques

Periodization

- As previously mentioned, a functional progression including neuromuscular markers is preferred over a traditional time-based model in determining when the athlete will progress safely into more advanced phases of rehabilitation.
- The primary goal of the performance enhancing phase is to restore muscular strength, endurance, power, cardiovascular endurance, and neuromuscular control/balance/proprioception. It also involves the introduction of progressive pivoting and cutting.
- Strength and conditioning parameters continue toward full restoration of specific strength and power utilizing a continuing nonlinear periodization model. Technical errors should have been corrected in the previous phase by using feedback measures.
- Variables of speed, resistance, recovery time, and exercise type are interchanged to avoid training adaptation plateau. Cycling through weekly or longer periods of variation can be used to maximize training adaptation.

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Milestones for progression into this phase include no joint effusion post exercise, normal running biomechanics at higher straight line speed, demonstrated strength testing of quadriceps/hamstrings 85% to 100% (isokinetic, relative strength index, limb symmetry index), hop testing symmetry (including single limb vertical jump height), single repeated jump-land with neutral knee/lumbo-pelvic control, force plate jump symmetry, and surgeons clearance/KT arthrometer/stress radiography.

Olympic Lifts Used in the Training Program

- All Olympic lifting continues with progressive resistance and speed.

Training Principles Used in the Design of the Program

- Conditioning sessions outlined in the previous phase continue to replicate game data. Game data illustrate repeat high intensity work bouts with minimal recovery ratios are required, with some positional differences.
- Maximum speed, over-speed, and speed-resistance training can be initiated with the aim of restoring normal sprint mechanics and increasing athletic performance. Care should be taken in weekly planning of these sessions in relation to acute soft tissue injury, and utilizing monitoring data as previously mentioned.
- Plyometric training (Figure 35-16) including single leg jump-land/depth jumps/bounding/repeat jump-land continue from the previous phase. Progression into rotational jumps and landing technique, decelerating bounds utilizing resistance bands, and advanced proprioceptive training landing on an unstable base can be introduced, and landing-knee position feedback given. Force plate data measuring single leg jump vertical ground reaction forces, and measured height need to be symmetrical to reduce reinjury risk, or contralateral limb injury risk.[9]
- The main component of this phase is introducing agility-based drills containing cutting/pivoting maneuvers (Figure 35-17) with feedback (video) in regards to knee and lumbopelvic control. Initial drills are slow speed, single direction change, noncontested drills to allow focus on knee positioning. Progression to higher speed, multidirectional changes and reactive drills, and

FIGURE 35-17. Agility/cutting Z drill.

eventually game simulated contested drills with multiple players are introduced. Positional specific drills can also be introduced, which simulate game-related data.[21] Throughout each progression, specific feedback on knee control is required.

Phase III: Sport-Specific Training

Periodization

- The final phase of sport-specific training is characterized by specific activities that emphasize returning the athlete to full game- and position-related function, and progressive integration into open reactive/multidirectional team drills and contact training. Emphasis is placed on successful return to previous specific functional levels, and prevention of reinjury.
- Milestones to progress into this phase are previously mentioned. These include strength testing, neuromuscular testing, ground reaction force testing, and clinical monitoring (e.g., effusion).
- Demonstrated excellent neuromuscular control of the knee and trunk during landing, cutting and pivoting is required and closely monitored, including control under fatigue.
- Psychological evaluation may be required if the athlete expresses a lack of confidence, or undue anxiety about injury risk. Final return to sport testing is required before medical clearance to sport, and involves several other functional tests. Listed below are functional tests that are used before clinical decision making.

Program Design/Performance Training Program

- Whilst there is a minimal specific evidence base for injured athletes in strength and conditioning principles during their rehabilitation phases, the final phase of training should incorporate established training principles, in this case of highly trained, healthy, young male footballers. Elements of power, strength, eccentric, plyometric, neuromuscular, sprint, and repeat high intensity training are required for rugby league, and most other football codes.
- Whilst strength and power training follows a game- and position-specific continuing overload-undulating/nonlinear program until maximum strength gains are symmetrical to preinjury levels, there is focus placed on periodized maximal strength, and maximal power phases. This may involve changing variables to shorter recovery periods with high load/low repetition to simulate actual game loads.
- During this phase, the injured athlete should have full integration into a normal preseason training schedule (assuming that the athlete is returning to sport at seasons start), whilst maintaining ongoing extra rehabilitation elements. These rehabilitation elements may include monitored strength/power deficits, but more importantly include continuing high-level neuromuscular/proprioceptive training, including training these elements under fatigue and in uncontrolled/reactive drills. Ongoing feedback regarding knee/lumbopelvic/trunk control is required.
- FIFA 11+, or similar proven preventative programs, can be incorporated into a regular dynamic warmup for the entire squad as an ongoing pretraining, and pregame ritual.[22]
- Monitoring, testing, and feedback of these elements continue after successful return to sport is made for a minimum period of 1 to 2 years, but should continue indefinitely if there are documented lapses of any element.
- Conditioning drills have game-specific focus on repeat high intensity bouts of exercise with high work/low recovery ratios. Maximal sprinting/return running drills containing 7 to 13 efforts lasting 7 to 8 seconds each effort, every 2 to 3 minutes continue, with as little as 5 seconds recovery between efforts. Distance covered with each effort vary between 6 and 10 m for front row forwards, and more than 21 m for outside backs and wide running forwards.[20]
- Preinjury data can be used to determine when the athlete approaches their preinjury cardiovascular endurance levels.
- Skill training under fatigue after conditioning drills is utilized to enhance ball handling skills, and decision-making in defensive and offensive game simulation. Attention and monitoring of active knee control during periods of fatigue is another clinical indicator of readiness to return to play.
- Movement based testing which is position specific has also been used as a clinical indicator of return to play readiness in NFL athletes returning from ACL reconstruction.[21]
- Contact and uncontrolled wrestling training are the final components of the returning athlete into full training, and represents uncontrolled blunt trauma risk to the knee in any direction.
- Maximal strength and functional testing is required to commence this sub-phase. As previously mentioned

hard bracing is not permitted in rugby league, which places high importance on excellent active knee control. Taping and soft bracing may enhance proprioceptive feedback, but will not offer rigid protection to knee hyperextension or varus joint moments sustained during contact training.
- Successful completion of a minimum of 3 to 4 weeks of full contact training is recommended before clearance to return to competitive games.

Sports Performance Testing

General Information

- General history
- Subjective questionnaires—online wellbeing/soreness scoring
- Medical history—current status, medications, and history
- Sports injury history—all previous injury history
- Surgical history—all surgical history
- Chronic conditions/medication
- Genetic conditions—hypermobility

Specific Tests

- Objective tests as per above text
- Physiological assessments—GPS heart rate data/maximum aerobic speed
- Body composition tests—weight and body fat composition
- Static/dynamic postural assessments—static star excursion test
- Dynamic muscle performance testing—hop/jump land/ground reaction force/video
- Movement performance testing—gait analysis/position specific testing
- Sport-specific testing—open training
- Others—MVC

Specific Criteria for Progression to the Next Stage to Determine Readiness for Rugby League

- As per text

Specific Criteria for Release to Unsupervised Complete Participation in Rugby League

- Objective criteria to release an athlete to commence competitive return to sport include no joint effusion after exercise sessions, normal running/sprinting/pivoting/cutting biomechanics including monitoring under fatigue, strength testing of quadriceps/hamstrings 90% to 100% (isokinetic, relative strength index, limb symmetry index), hop testing symmetry (including single limb vertical jump height), single repeated jump-land with active knee control (including monitoring under fatigue), force plate/ground reaction force jump symmetry, surgeons clearance (including KT arthrotometer/stress radiography), position-specific movement testing, and asymptomatic completion of open skills/contact training over at least 3 to 4 weeks. See Figure 35-18 for an example of a return to training program.

Recommended Ongoing Exercises

- Monitored strength/power deficits
- High level neuromuscular training
- Lumbo-pelvic control
- Regular monitoring (GRF—jump and hop tests and video)

Evidence

Heijne A, Werner S: Early versus late start of open kinetic chain quadriceps exercises after ACL reconstruction with patella tendon or hamstring grafts: A prospective randomized outcome study. *Knee Surg Sports Traumatol Arthrosc* 15:402–414, 2007.

A randomized controlled study comparing 68 patients' outcomes after ACL reconstruction. Patients were randomly allocated to early (4th postoperative week) and late (12th postoperative week) start of OKC quadriceps exercises in both patella tendon and hamstring tendon subgroups. Preoperative and postoperative measures of ROM, anterior knee laxity, postural sway, thigh muscle torques, and anterior knee pain were evaluated. Early OKC with hamstring tendon graft showed a significantly increased anterior knee laxity over time (Randomized controlled trial; Level II evidence).

Kinder A, Jenkins W, Urch S, et al: Rehabilitation following knee dislocation with lateral side injury: Implementation of the knee symmetry model. *N Am J Sports Phys Ther* 5:155–165, 2010.

A prospective case series of 21 patients with knee dislocation and lateral side injury, implementing the Knee Symmetry Model of rehabilitation involving symptomatic restoration of ROM and weight-bearing progression rather than a timeframe-based approach. Outcome data and subjective knee scores (International Knee Documentation Committee and modified Noyes survey scores) showed excellent long-term stability, normal ROM and strength, and a high level of function (Case series; Level IV evidence).

Lunden J, Bzdusek P, Monson J, et al: Current concepts in the recognition and treatment of posterolateral corner injuries of the knee. *J Ortho Sports Physical Ther* 40:502–516, 2010.

A current expert opinion based review of concepts of rehabilitation of posterolateral corner injuries (Diagnosis/therapy; Level V evidence).

Myer G, Martin L, Ford K, et al: No association of time from surgery with functional deficits in athletes after anterior cruciate ligament reconstruction: Evidence for objective return to sport criteria. *Am J Sports Med* 40:2256–2263, 2012.

A prospective study of 33 athletes with unilateral ACL reconstruction cleared by a physician to return to sport, measuring unilateral force development (vertical jump height) and absorption (vertical ground reaction force) deficits. Symmetry deficits persist in athletes after return to sports and are independent of time after reconstruction (Case series; Level IV evidence).

Reimen M, Lorenz D: Integration of strength and conditioning principles into a rehabilitation program. *Int J Sports Phys Ther* 6:241–253, 2011.

A current expert opinion based review of concepts of strength and conditioning principles in rehabilitation of injured athletes (Level V evidence).

Coaching Session: Skills Rehab

Start: 10/01/13 7:00:00am

End: 10/01/13 8:00:00am

Venue: TBA

Major Objective:

	Group	Exercise/Drill	Time	Duration	Drill Objective	Players - Modified	Coaches
1	All	Mapping Drill/3 plays	7:00am	10mins	Communication / spacing		
2	All	Leg Swings	7:10am	5mins	Physical preparation		
3	Forwards	Attack - Position Specific	7:15am	20mins	Carry - lean into contact		
					- 2 on 1 Def shooting		
					- 1Bs 2 vs 3 pads with Rooster option		
					- Ruck Plays- wedge / snap / 12 / Viking / Block		
					- Static then rolling thru pads		
4	Backs	Attack - Position Specific	7:15am	20mins	- Long passing		
					- 3 v 3 kick returns		
					Kickers:		
					- 1 leg to step thru / numbers grid		
					Add pad		
					Catchers:		
					Throw routine: hands high / chest mark / lying on ground		
					- Pad work		
					All: Kickers thru poles to 1,2,3,4.		
					- catchers get interference		
					- contested grabs 1 v 1		
5	All	5 v 4 - Defence	7:40am	10mins	Use whistle	Shoulder Boys- Mod skills	
					Get fwd / nominate		
6	All	Kick ChaseGame	7:50am	15mins	Rules:	1 v 2, 1 v 3, 2 v 3	
					- kick inside own 1/2 for 20m tackle 1pt		
					- inside 10m tackle 2pts	Shoulder Boys- Mod skills	
					- kick in opposition 1/2 for repeat set 3pts		
					- 4pts for a try		

Coaching Session: Conditioning

Start: 22/01/13 7:00:00am

End: 22/01/13 8:00:00am

Venue: DFS 1

Major Objective:

	Group	Exercise/Drill	Time	Duration	Drill Objective	Players - Modified	Coaches		
1	**Full Training**	**Conditioning**	**7:00am**	**6mins**	**6 x 10m Returns in 36sec go on 1min**				
					Group 1 - 32m				
					Group 2 - 31m x 8 in 6sec go on 12sec				
					Group 3 - 30m Start off ground				
					6 x 10m Returns in 36sec				
					Total 488m				
					2min recovery				
2	**Full Training**	**Conditioning**	**7:00am**	**8mins**					

FIGURE 35-18. A sample return to training program.

					Group 1											
					Back 4m, Fwd 20m hit ground, back 10m hit ground,											
					sprint 20m in 15sec, jog back to start go on 35sec											
					Group 2											
					Back 3m, Fwd 20m hit ground, back 10m hit ground											
					sprint 20m in 15sec, jog back to start go on 35sec											
					Group 3											
					Back 2m, Fwd 20m hit ground, back 10m hit ground											
					sprint 20m in 15sec, jog back to start go on 35sec											
					Total 516m											
					3min recovery											
3	Full Training	Conditioning	7:00am	7mins	Up 10m hit ground back 10m then up 10m hit ground											
					then sprint back											
					Group 1 - 26m											
					Group 2 - 24m											
					Group 3 - 22m											
					x 8 in 15sec walk back to start go on 30sec											
					Total 464m											
					3min recovery											
4	Full Training	Conditioning	7:00am	8mins	MAS x 4 With Football											
					Group 1 - 83m and 16m return											
					Group 2 - 78m and 14m returns											
					Group 3 - 73m and 12m returns											
					6 x 10m returns in 36sec go on 1min											
					MAS x 4 With Football											
					Group 1 - 83m											
					Group 2 - 78m No Returns											
					Group 3 - 73m											
					Total 884m											
					3min recover y											
5	Full Training	Conditioning Games	7:00am	8mins	Games with Coaches:											
					- partner offside touch											
					- two games											
6	Full Training	Conditioning	7:00am	29mins	Repeat in reverse but no game											

Training Groups

Multiple-Choice Questions

QUESTION 1. Which choice of stage progression is recommended for late stage rehabilitation PLC reconstruction in athletes?

A. Timeline progression only
B. Functional progression including milestone testing
C. Surgeons clearance only
D. Strength testing only

QUESTION 2. Which testing criteria are not recommended to provide medical clearance to competitive contact sport?

A. Strength testing (isokinetic, relative strength index, limb symmetry index)
B. Hop testing
C. Positional specific movement testing
D. None of the above

QUESTION 3. What exercises are recommended that the athlete continues after returning to sport?

A. Strength deficits
B. Neuromuscular training
C. Cutting/pivoting with knee position feedback
D. All of the above

QUESTION 4. Which loads must be avoided during postsurgical rehabilitation for PLC injury?

A. Flexion
B. Valgus loading
C. Varus loading and hyperextenion
D. None of the above

Answer Key

QUESTION 1. Correct answer: **B** (see Phase I: Advanced Strength and Conditioning Programs)

QUESTION 2. Correct answer: **D** (see Phase I: Sport Performance Testing)

QUESTION 3. Correct answer: **D** (see Phase III: Sport-Specific Training)

QUESTION 4. Correct answer: **C** (see Introduction)

Chapter 36

Leg Pain in the Athlete: Stress Fractures, Medial Tibial Stress Syndrome, and External Compartment Syndromes

INTRODUCTION

Timothy S. Mologne, MD, and Kari Sturtevant, DPT

Epidemiology

- Leg pain is a common complaint in athletes.
- There is no disparity between men and women, except stress fractures are more common in women.
- Leg pain can be seen in athletes in all sports, but is especially common in endurance sports, particularly running.

Pathophysiology

Intrinsic Factors

- Excessive foot pronation combined with repetitive impact activity
- Hormonal imbalance
- Female endurance athletes (anorexia, amenorrhea, osteopenia)[1,2]
- Poor nutrition
- Metabolic disorders
- Abnormal anatomical relationship between the popliteal artery and fascia and muscles in the popliteal fossa (popliteal artery entrapment syndrome)

Extrinsic Factors

- Overuse
- Acute increase in duration and intensity of training without appropriate conditioning
- Repetitive loading
- Improper footwear
- Repetitive running on hard surfaces

Classic Pathological Findings

- Inflammatory process of the periosteum and tendinous attachments of the soleus, flexor digitorum longus, and deep crural fascia along the posteromedial aspect of the distal two thirds of the tibia: medial tibial stress syndrome[3]
- Imbalance in bone turnover with more bone resorption than bone production: stress fracture[2]
- Muscle ischemia related to: chronic compartment syndrome[4]
- Entrapment of the popliteal artery by medial displacement of the artery by the medial head of the gastrocnemius muscle: popliteal artery entrapment syndrome[5]
- Entrapment of various motor and sensory nerves in the leg and ankle: nerve entrapment syndrome
- Bone formation in the interosseous ligament between the tibia and fibula following an ankle or tibial fracture: tibiofibular synostosis
- Fascial defect in the lateral leg compartment at the site of the superficial branch of the peroneal nerve becoming superficial: muscle herniation with possible associated chronic exertional compartment syndrome[4]

Clinical Presentation

History

- Activity-related aching pain along the posteromedial aspect of the distal two thirds of the tibia: posteromedial tibial stress syndrome
- Activity-related pain on the tibia: stress fracture
- Leg aching during or after exercise that usually occurs after the same duration of exercise. The pain does not resolve immediately after rest: chronic exertional compartment syndrome
- Possible postexercise paresthesias: chronic exertional compartment syndrome
- Cramping pain and paresthesias with exercise, which are relieved with rest: popliteal artery entrapment syndrome

Physical Examination

- Diffuse tenderness to palpation along the distal two thirds of the posteromedial aspect of the tibia: medial tibial stress syndrome
- Pain in the posteromedial tibia with toe raises and resisted plantar flexion: medial tibial stress syndrome
- More focal tenderness along the tibia with possible swelling in the same area: stress fracture
- Increased pain with a bending or twisting force is applied to the tibia: stress fracture
- Physical examination is usually normal in patient with chronic exertional compartment syndrome, but may demonstrate firm, tense leg compartments and possible paresthesias in a specific nerve distribution, depending on the compartment and pressures in the compartment that contains the nerve.
- The physical examination is usually normal in patients with popliteal entrapment syndrome. With the knee extended, pulses may diminish or obliterate with passive ankle dorsiflexion or active plantar flexion. Pulse may be best assessed with Doppler ultrasound.

Imaging and Other Diagnostic Studies

- Radiographs of the leg
- Bone scan (may be helpful in medial tibial stress syndrome and stress fractures) (Figure 36-1)
- Magnetic resonance imaging (MRI; helpful for stress fractures, medial tibial stress syndrome, and exertional compartment syndrome) (Figure 36-2)
- Arteriogram in cases of suspected popliteal artery entrapment syndrome and in patients thought to have vascular claudication
- Leg compartment pressure measurements at rest and 1 and 5 minutes after exercise (diagnostic for exertional compartment syndrome)[4]
- Doppler ultrasound may be used to assess ankle pulses in the workup for suspected popliteal artery entrapment syndrome.

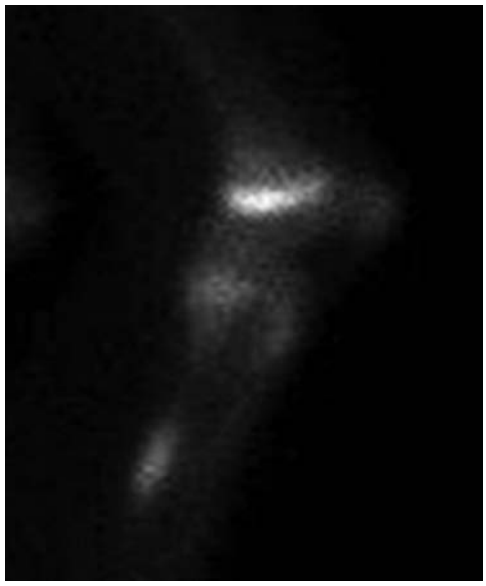

FIGURE 36-1. Bone scan showing mild increased uptake along the posteromedial aspect of the distal third of the tibia in an elite runner diagnosed with posteromedial tibial stress syndrome.

Differential Diagnosis

- Medial tibial stress syndrome
- Tibial stress fracture
- Chronic exertional compartment syndrome
- Popliteal artery entrapment syndrome
- Nerve entrapments
- Gastroc-soleus strain
- Plantaris tear
- Ruptured Baker's cyst
- Tibiofibular synostosis
- Fascial defect with muscle herniation

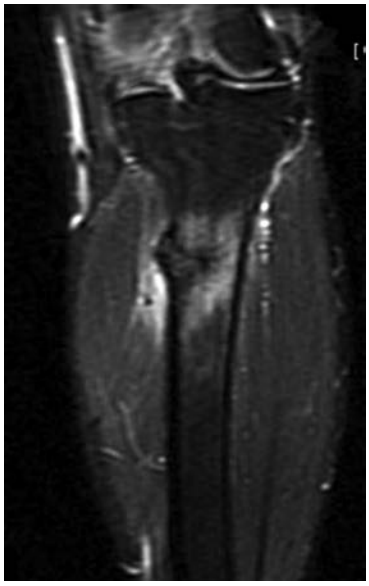

FIGURE 36-2. Magnetic resonance image of a stress fracture of the proximal medial tibia.

- Lumbosacral disc herniation with radiculopathy
- Vascular claudication (elder athletes with possible peripheral vascular disease)
- Neurogenic claudication from spinal stenosis

Treatment

Nonoperative Management

- REST
- Cross-training
- Decrease in training intensity and duration
- Change in training surface
- Nonsteroidal antiinflammatory agents
- Ice
- Heel cord stretching
- Orthotics for excessive foot pronation
- Education on gradual progression in training and conditioning

Guidelines for Choosing Among Nonoperative Treatments

- Virtually all causes of leg pain in athletes, with the exception of chronic exertional compartment syndrome and popliteal artery entrapment syndrome, are treated conservatively as an initial step.

Surgical Indications

- At least 4 months of rest and activity modification with recurrence of symptoms once activities and sports activities are restarted (medial tibial stress syndrome)
- Stress fractures of the anterior tibial cortex that remain symptomatic and show signs of delayed or nonunion despite 6 months of treatment
- Chronic exertional compartment syndrome is not effectively managed with nonsurgical treatments except rest and activity modifications. Surgery is the best option to allow athletes to return to their respective sports.
- Claudication symptoms in patients found to have popliteal artery entrapment syndrome
- Persistent symptoms related to specific nerve compressions that do not respond to conservative treatment.

Evidence

Bennell K, Matheson G, Meeuwisse W, et al: Risk factors for stress fractures. *Sports Med* 28(2):91–122, 1999.

This article is a literature review on stress fractures and concludes that although stress fractures result from repetitive loading, no clear association has been determined between stress fractures and the duration or intensity of training. Menstrual disturbances, caloric restriction, lower bone density, muscle weakness, and leg length differences are risk factors for stress fracture. (Level X evidence)

Mubarak S, Gould R, Lee Y, et al: The medial tibial stress syndrome. A cause of shin splints. *Am J Sports Med* 10:201–205, 1982.

This case series of 12 patients with posteromedial leg pain found normal compartment pressure measurements. Mild increased uptake on a bone scan was present in two of eight patients (25%). Biopsy material of the affected area in two patients treated surgically with a deep posterior compartment fasciotomy is described as showing inflammation and vasculitis. (Level X evidence)

Pedowitz R, Hargens A, Mubarak S, et al: Modified criteria for the objective diagnosis of chronic compartment syndrome of the leg. *Am J Sports Med* 18:35–40, 1990.

This retrospective study evaluated 45 patients diagnosed with chronic compartment syndrome. A fascial herniation of muscle was found in 46%. The authors defined intramuscular compartment pressure criteria to diagnose an chronic exertional compartment syndrome of the leg as (1) a pre-exercise pressure greater than or equal to 15 mmHg; (2) a 1-minute postexercise pressure of great than or equal to 30 mmHg; or (3) a 5-minute postexercise pressure greater than or equal to 20 mmHg. (Level X evidence)

Pell R, Khanuja H, Cooley R: Leg pain in the running athlete. *J Am Acad Orthop Surg* 12(6):396–404, 2004.

This review article outlines and discusses the evaluation and management of various causes of leg pain in runners. (Level X evidence)

Stager A, Clement D: Popliteal artery entrapment syndrome. *Sports Med* 28(1):61–70, 1999.

This review article discusses the pathoanatomy, demographics, and clinical presentation of patients with exercise-induced leg pain caused by entrapment of the popliteal artery along the posterior aspect of the knee. (Level X evidence)

Multiple Choice Questions

QUESTION 1. Intrinsic factors contributing to leg pain in the athlete include:

A. Poor nutrition
B. Being female
C. Abnormal hormone balance
D. All of the above

QUESTION 2. Which of the following scenarios is *least* likely to result in leg pain?

A. A 42-year-old male runner who recently increased his miles run per week from 25 to 35 and improved his pace from a 10-minute mile to an 8-minute mile
B. A 26-year-old woman training for an ironman who now has infrequent menstrual cycles and is concerned about her weight and body image
C. A 32-year-old female cyclist who recently purchased a new road bicycle, had it custom fit, and has now increased her mileage per week by 10% with similar intensity
D. A 21-year-old man with a history of medial tibial stress fractures who has recently returned to running with old shoes and displays moderate pronation while running

QUESTION 3. Which of the following is *not* a surgical indication?

A. Conservative treatment has failed to relieve specific nerve compressions.
B. Following 4 months of treatment, stress fractures of the anterior tibial cortex remain symptomatic.
C. Following 4 months of rest and activity modification, familiar symptoms are experienced once sport activities are resumed.
D. Claudication symptoms persist in a patient with popliteal artery entrapment.

QUESTION 4. Which of the following injuries is *not* initially treated conservatively?

A. Chronic exertional compartment syndrome
B. Tibiofibular synostosis
C. Medial tibial stress fracture
D. Decreased sensation in the area of the leg consistent with the superficial fibular nerve

QUESTION 5. Which of the following diagnostic images would be useful for an athlete with complaints of leg pain?

A. MRI
B. Radiograph
C. Doppler ultrasound
D. CT myelogram

Answer Key

QUESTION 1. Correct answer: **D** (see Pathophysiology: Intrinsic Factors)

QUESTION 2. Correct answer: **C** (see Pathophysiology)

QUESTION 3. Correct answer: **B** (see Treatment: Surgical Indications)

QUESTION 4. Correct answer: **A** (see Treatment: Guidelines for Choosing Among Nonoperative Treatments)

QUESTION 5. Correct answer: **D** (see Clinical Examination: Imaging and Other Diagnostic Studies)

NONOPERATIVE REHABILITATION OF MEDIAL TIBIAL STRESS SYNDROME

Mark F. Reinking, PT, PhD, SCS, ATC, and L. Tyler Wadsworth, MD

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION OF MEDIAL TIBIAL STRESS SYNDROME

- Let the athlete's leg pain guide the return to activity
- Gradual return to athletic activity
- Address entire kinetic chain biomechanics

Phase I (weeks 0 to 2): Acute Phase

Protection

- If the athlete has medial tibial pain with walking ambulation, crutches should be used until the athlete can walk without pain.

Management of Pain and Swelling

- Icing and electrical stimulation can be used to control pain complaints.
- Some athletes report improvement in pain with use of a compressive sleeve worn over the leg, although there is no evidence to support or refute use of this approach.

Techniques for Progressive Increase in Range of Motion

If the athlete shows impairments of range of motion (ROM) at the ankle, the clinician needs to identify if the limitation is a result of muscle length, joint limitation, or both. The appropriate intervention would be selected based on that differential.

Manual Therapy Techniques

- If joint ROM limitations, joint mobilization should be applied appropriately in terms of grade and direction.

Soft Tissue Techniques

- The muscles that have been named as potential contributors to medial tibial stress syndromes (MTSS) include soleus, posterior tibialis, flexor digitorum longus, and flexor hallices longus.[1-5]

- Newsham[6] demonstrated a decrease in MTSS pain using manual techniques to reduce hypertonicity in the deep posterior compartment of the leg.
- Callison[7] presented evidence that the addition of acupuncture to a standard rehabilitation program for medial tibial stress syndrome significantly decreased pain and medication use.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Gastrocnemius and soleus stretching as indicated by muscle length testing

Other Therapeutic Exercises

- Relative rest from the offending weight-bearing activities is important in Phase I. Decrease the volume of impact weight-bearing exercise by at least 50%.
- Add low-impact cross-training (pool running, cycling, elliptical machine) to maintain cardiorespiratory fitness.

Activation of Primary Muscles Involved

- Newsham[6] recommended restoring muscle balance of the toe flexors and extensors using exercise to facilitate toe extension and short foot exercises to improve the strength of the foot intrinsics. If other muscle weakness of the crural muscles was identified in the initial examination, this should be addressed.

Sensorimotor Exercises

- No evidence to support this for MTSS, but if the athlete's ground-based training is altered because of leg pain, these exercises can minimize loss of sensorimotor performance. Begin with static balance exercises such as single leg stand on floor with eyes open and progress to less stable surface and eyes closed.

Open and Closed Kinetic Chain Exercises

- Avoid any impact loading that is painful. If the athlete can perform closed kinetic chain exercises without leg pain, then these should not be restricted.

Techniques to Increase Muscle Strength, Power, and Endurance

- Niemuth[8] identified hip abductor muscle weakness in a group of recreational runners with lower limb overuse injuries.
- Address any muscle imbalances in the lower kinetic chain. This should be based on careful manual muscle testing and observational gait analysis.

Milestones for Progression to the Next Phase

- Pain-free walking ambulation
- Minimal pain to palpation along posteromedial tibial crest

Phase II (weeks 3 to 4): Rehabilitation Phase

Orthotics

- Consideration should be given for orthotic fabrication based on lower extremity movement patterns and function.
- Some evidence suggests that an excessively pronated foot may increase the risk for MTSS.[9]
- Other evidence suggests both over the counter and custom foot orthotics decrease pain in athletes with MTSS.[10,11]
- Orthotic decision making is based on athlete preference, foot type, sport activity, and arch taping trial.

Management of Pain and Swelling

- Icing after exercise

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Same as described in Phase I, but progressing to more aggressive joint techniques if ROM impairment persists.

Soft Tissue Techniques

- Same as described in Phase I.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Same as described in Phase I.

Sensorimotor Exercises

- Progress athlete to higher demand static balance exercise including single leg stand on unstable surface with upper extremity challenges including diagonal movements, resisted upper extremity exercise, Bodyblade, and rebounder.

Open and Closed Kinetic Chain Exercises

- Progress resistance from Phase I and add multiplanar closed chain movements in Phase II, including multidirectional lunges, lunge with trunk rotation, squats with upper extremity diagonal patterns.

Techniques to Increase Muscle Strength, Power, and Endurance

- Adjust exercise dosage appropriate to functional demand of impaired muscles.

Plyometrics

- If athlete is pain free with all ground based exercises, begin early plyometric training[12] with mini-trampoline

double leg hops, double leg drop squats, and double leg decline squats. These exercises must be pain free and performed no more than 3 times/week on alternate days.

Functional Exercises

- Begin progression to return to running progression with a walk-jog-run progression. See sample progression in Box 36-1.
- An athlete who has mild tenderness to palpation and symptoms that do not worsen with weight-bearing exercise can progress training as tolerated.

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or Other More Invasive Intervention

- Positive compartmental pressure study: Athletes who show persistence of leg pain with weight-bearing activities and inability to progress through return to running progression should be tested for chronic exertional compartment syndrome.

Milestones for Progression to the Next Phase

- No pain with palpation along posteromedial tibial crest
- Minimal to no pain with early plyometrics and walk-jog-run progression. An athlete who is doing most training in the pool may be allowed to return to competition but continue with functional progression during training time.

Phase III (weeks 4 to 8): Functional Training Phase

Management of Pain and Swelling

- Icing after running

Sensorimotor Exercises

- Progress athlete to dynamic balance activities using BOSU ball, slide board, balance beam.

Open and Closed Kinetic Chain Exercises

- Progress the challenge, intensity and speed of the multiplanar closed chain exercises introduced in Phase II.

Plyometrics

- Progress to higher level plyometric exercises including ankle hops on floor (double to single leg), depth jumps, box jumps, squat jumps, tuck jumps, and bounding.

Functional Exercises

- Continue with walk-jog-run progression.

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- Completion of functional progression
- Performance of all plyometric exercises without tibial pain

TIMELINE 36-1: **Nonoperative Rehabilitation of Medial Tibial Stress Syndrome (MTSS)**

PHASE I (weeks 0 to 2)	PHASE II (weeks 3 to 4)	PHASE III (weeks 4 to 8)
• Weight bearing as tolerated • Icing and interferential electrical stimulation for pain control • Joint mobilizations as indicated • Soft tissue mobilization/myofascial techniques to medial crural tissues • Gastrocnemius and soleus stretching as indicated • Cross-training activities • Short foot exercises • Hip muscle strengthening (lateral rotators, abductors) as indicated • Nonimpact balance exercises • Hike	• Pain-free walking ambulation • Orthotic fabrication as indicated • Icing and interferential electrical stimulation following exercise • Joint mobilizations as indicated • Soft tissue mobilization/myofascial techniques to medial crural tissues • Gastrocnemius and soleus stretching as indicated • Cross-training activities • Short foot exercises • Hip muscle strengthening (lateral rotators, abductors) as indicated • Nonimpact higher demand balance exercises • Multiplanar nonimpact closed kinetic chain exercises • Initiate early plyometric exercise • Initiate walk-jog-run functional progression	• Walk-jog-run progression • Icing and interferential electrical stimulation following exercise • Gastrocnemius and soleus stretching as indicated • Hip muscle strengthening (lateral rotators, abductors) as indicated • Higher demand dynamic balance exercises • Increase training volume of multiplanar closed kinetic chain exercises • Plyometric sequence

BOX 36-1 Walk-Jog-Run Progression

Rules of Progression:

- Stretching: gastroc, soleus, hamstring, quad, IT band before and after run (2 × 30 seconds each).
- If you have pain during run, slow to a brisk walk and complete the workout time. *Do not* proceed to the next step until you are able to perform that level without pain.
- Cross-training options: pool running, elliptical trainer, stationary cycling, swimming
- Minor shin soreness after running may occur but should dissipate within 1 to 2 hours. If not, do not progress to the next step!
- Perform weeks 1 to 2 on a treadmill, and then progress to overground exercise.
- *Do not run through pain!*

1 DAY	DISTANCE/MODE	INTENSITY	2 TIME	COMPLETED
1	Walk 3 min	4.0 MPH	14 min	
	Jog 2 min	6.0 MPH		
	Walk 3 min	4.0 MPH

28	Day Off			

Week 5: Run on consecutive days; gradually increase mileage.
Week 6: Resume full training as long as pain free.

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or Other More Invasive Intervention

- Persistence of pain with weight-bearing activities
- Inability to complete functional progression to running secondary to pain

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Pain-free running on successive days
- No pain with palpation along the posteromedial tibial border (MTSS)

Evidence

Eickhoff CA, Hossain SA, Slawski DP: Effects of prescribed orthoses on medial tibial stress syndrome in collegiate cross country runners. *Clin Kines* 54(4):76–80, 2000.

One hundred sixty-four collegiate cross-country athletes completed a survey on the effect of presecribed foot orthoses for medial tibial stress syndrome. Overall, 88% of athletes with MTSS symptoms reported a favorable effect from orthotic use. (Level IIb evidence)

Galbraith RM, Lavallee ME: Medial tibial stress syndrome: conservative treatment options. *Curr Rev Musculoskelet Med* 2(3):127–133, 2009.

This narrative review summarizes the published literature regarding conservative treatment options for medial tibial stress syndrome. (Level V evidence)

Herring KM: A plyometric training model used to augment rehabilitation from tibial fasciitis. *Curr Sports Med Rep* 5(3):147–154, 2006.

This methodological paper proposes a plyometric training model to incorporate into the rehabilitation of atheltes with medial tibial stress synrome (tibial fasciitis). Although the authors suggested that this model be subject to research, no evidence of the effectiveness of the model was presented in the paper. (Level V evidence)

Loudon JK, Dolphino MR: Use of foot orthoses and calf stretching for individuals with medial tibial stress syndrome. *Foot Ankle Spec* 3(1):15–20, 2010.

This prospective cohort study included 23 runners with symptoms of MTSS. All participants received interventions, including off-the-shelf foot orthotics and calf stretching. Of the 23 runners, 15 had a 50% reduction of pain in 3 weeks of intervention. The duration of MTSS symptoms was a significant factor that was associated with intervention effectiveness. The authors recommended that treatment for runners with MTSS may include off-the-shelf orthotics and calf stretching. (Level IIb evidence)

Moen MH, Rayer S, Schipper M, et al: Shockwave treatment for medial tibial stress syndrome in athletes: a prospective controlled study. *Br J Sports Med* 46(4):253–257, 2012.

This prospective observation trial included 42 athletes from two sports medicine clinics diagnosed with MTSS by the same sports medicine specialist. All athletes form one clinic were treated with a graded running progression, and the athletes at the second clinic also performed the graded running progression and received extracorporeal shockwave therapy (ESWT). These athletes received a total of five ESWT treatments in 9 weeks. The authors found that the subjects in the ESWT group returned to runner sooner than those who performed the running progression only. (Level IIb evidence)

Moen MH, Tol JL, Weir A, et al: Medial tibial stress syndrome: A critical review. *Sports Med* 39(7):523–546, 2009.

This systematic review provided a summary of the literature on medial tibial stress syndrome, including etiology, biomechanics, histology, examination, imaging, risk factors, therapy, conservative and surgical treatment, and prevention. (Level IIIa evidence)

Newsham K: A neuromuscular intervention for exercise related medial leg pain. *J Sport Rehabil* 21(1):54–62, 2012.

The quasi-experimental, nonequivalent control group study evaluated the effectiveness of a neuromuscular intervention for exercise related medial leg pain (ERMLP). Thirteen athletes with ERMLP symptoms were divided into a treatment group (N = 7) and a control group (N = 6). The treatment group received manual therapy to decrease trigger poin pain in medial leg and retraining of toe extensors and flexors. The treatment group exhibited decreased ERMLP pain with activity, and an increase in their algometer pressure threshold. (Level IV evidence)

Multiple Choice Questions

QUESTION 1. Which of the following muscles has not been implicated in the etiology of medial tibial stress syndrome?

A. Soleus
B. Posterior tibialis
C. Flexor hallicus longus
D. Anterior tibialis

QUESTION 2. Early plyometric exercises such as ankle bounces on a mini-trampoline should be introduced in which rehabilitation Phase?

A. I
B. II
C. III
D. IV

QUESTION 3. When an athlete has persistent medial leg pain that is not responding to nonsurgical intervention, the most appropriate action is which of the following?

A. Casting of the foot and ankle
B. Continue with functional return to running progression
C. Compartmental pressure testing
D. Nerve conduction velocity testing

Answer Key

QUESTION 1. Correct answer: **D** (see Phase I)

QUESTION 2. Correct answer: **B** (See Phase II)

QUESTION 3. Correct answer: **C** (see Phase II)

NONOPERATIVE REHABILITATION OF TIBIAL STRESS FRACTURE

Mark F. Reinking, PT, PhD, SCS, ATC, and L. Tyler Wadsworth, MD

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- Determine whether the stress fracture is at a high- or low-risk location.
- Allow adequate protection and time for clinical healing (and radiographic healing as indicated).
- Let the athlete's leg pain guide the return to activity.
- Gradual return to athletic activity.

Phase I (weeks 0 to 2–6): Acute Phase

Protection

- In the leg, the tibial plateau, proximal posteromedial tibia, medial distal tibial diaphysis, and fibular stress fractures are considered low risk.
- Stress fractures of the anterior mid-tibia and medial malleolus have a high risk of nonunion, recurrence, and fracture completion.
- For high-risk stress fractures of the anterior mid-tibia and medial malleolus, immobilization and non–weight

bearing are required and some athletes may require surgical treatment.

- Low-risk stress fractures have a low potential for nonunion or fracture completion, or other complication. Athletes with low-risk stress fractures may be allowed to continue limited participation if they are willing to accept the risk of prolonged symptoms and fracture extension or progression to complete fracture.
- If the athlete with a low-risk stress fracture has tibial pain with ambulation, crutches with or without fracture brace should be used until the athlete can walk without any increase in pain or discomfort. A pneumatic air brace is used for athletes who tolerate weight-bearing without increase in discomfort and has been shown to reduce time to unrestricted activity in low-risk stress fractures.[1]
- Underlying causes for stress fracture should be elicited, including rapid increases in training volume and/or intensity, history of menstrual irregularity in female athletes, nutritional inadequacy (especially the intake of total calories and calcium), condition and type of running shoes.
- Documented risk factors for recurrent stress fractures include high longitudinal arch of the foot, leg-length inequality, excessive forefoot varus, and high weekly training mileage.[2]
- Consideration should be given to testing vitamin D levels, as low vitamin levels have been linked to an increased risk for stress fracture.[3] Treatment of nutritional inadequacies is important but there is no evidence that routine treatment with calcium or vitamin D in individuals who are not deficient accelerates stress fracture healing.

Management of Pain and Swelling

- Icing and electrical stimulation can be used to control pain complaints.
- Analgesics should not be used to allow weight-bearing activity, but patients who have pain can be treated with analgesics. Although there is some concern regarding potential interference of bone healing caused by nonsteroidal antiinflammatory drugs (NSAIDs), there is no evidence to date to support or disprove this theory.
- There are no controlled trials of electromagnetic field or ultrasonic bone stimulation in treatment of low-risk stress fractures showing improvement in healing rates when these technologies are used.[4] However, treatment of stress fractures of the anterior mid-tibia with pulsed electromagnetic fields is widely employed despite limited evidence specific to stress fracture.

Techniques for Progressive Increase in Range of Motion

Only activities that do not cause pain progression are allowed during this stage for low-risk stress fractures, and no pain is permitted in high-risk stress fractures. If the athlete shows impairments of ROM at the ankle, the clinician needs to identify if the limitation is a result of muscle length, joint limitation, or both. The appropriate intervention would be selected based on that differential

Manual Therapy Techniques

- If joint ROM limitations, joint mobilization should be applied appropriately in terms of grade and direction.

TIMELINE 36-2: **Nonoperative Rehabilitation of Low-Risk Tibial Stress Fracture**

PHASE I (weeks 1 to 2)	PHASE II (weeks 3 to 4)	PHASE III (weeks 4 to 8)
• Only pain-free weight bearing advised • Pneumatic brace may be used to allow pain-free weight-bearing activities • Icing and interferential electrical stimulation for pain control • Joint mobilizations as indicated • Soft tissue mobilization/myofascial techniques to medial crural tissues • Gastrocnemius and soleus stretching as indicated • Cross-training activities such as pool running as tolerated • Short foot exercises • Hip muscle strengthening (lateral rotators, abductors) as indicated • Nonimpact balance exercises • Hike	• Pain-free walking ambulation in pneumatic brace • Orthotic fabrication as indicated • Icing and interferential electrical stimulation following exercise • Joint mobilizations as indicated • Soft tissue mobilization/myofascial techniques to medial crural tissues • Gastrocnemius and soleus stretching as indicated • Cross-training activities may include non-impact activities such as pool running, elliptical trainer, StairMaster, stationary cycling • May introduce walk-jog-run progression if this does not exacerbate pain • Short foot exercises • Hip muscle strengthening (lateral rotators, abductors) as indicated • Nonimpact higher demand balance exercises • Multiplanar nonimpact closed kinetic chain exercises • Initiate walk-jog-run functional progression	• Walk-jog-run progression • Icing and interferential electrical stimulation following exercise • Gastrocnemius and soleus stretching as indicated • Hip muscle strengthening (lateral rotators, abductors) as indicated • Higher demand dynamic balance exercises • Increase training volume of multiplanar closed kinetic chain exercises • Plyometric sequence

Soft Tissue Techniques

- Address co-existing soft tissue comorbidities including medial tibial stress syndromes (MTSS) and myofascial trigger points.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Gastrocnemius and soleus stretching as indicated by muscle length testing.

Other Therapeutic Exercises

- Relative rest from any painful weight-bearing activities is important in Phase I.
- Pool running can be employed to maintain cardiorespiratory fitness if this can be done without exacerbating the athlete's pain.

Activation of Primary Muscles Involved

- Non–weight-bearing, pain-free range of motion exercises of the hip, knee, ankle, and foot can be performed daily to preserve joint range of motion and soft-tissue length.

Sensorimotor Exercises

Begin with static balance exercises such as single leg stand on floor with eyes open and progress to eyes closed when athlete can maintain balance for 20 to 30 seconds. Athlete should then be progressed to less stable surfaces (foam, BOSU Ball, DynaDisc), first with eyes open and then with eyes closed.

Open and Closed Kinetic Chain Exercises

- Only pain-free closed kinetic chain exercises are allowed in Phase I. Open kinetic chain exercises targeted at muscle weakness identified in the initial examination is permitted unless painful at the fracture location. No impact loading exercises are allowed in this Phase.

Techniques to Increase Muscle Strength, Power, and Endurance

- Niemuth[5] identified hip abductor muscle weakness in a group of recreational runners with lower limb overuse injuries. Address any muscle imbalances in the lower kinetic chain that can be treated without exacerbating stress fracture pain. This should be based on careful manual muscle testing and observational gait analysis.

Milestones for Progression to the Next Phase

- Pain-free walking ambulation
- No tenderness to palpation or percussion, negative provocative maneuvers (hop test, pain on tuning fork examination, pain with fulcrum testing) is allowed for high-risk stress fractures on physical examination.

Phase II (weeks 2 to 12): Rehabilitative Phase

Protection

- Pneumatic air brace for weight-bearing activities as needed.
- Only activities that do not worsen pain are allowed.

Orthotics

- Consideration should be given for orthotic fabrication based on lower extremity movement patterns and function.
- There is no evidence that over-the-counter or custom foot orthotics are useful in secondary prevention of stress fracture in athletes, although there is a high degree of acceptance and satisfaction among runners who use orthotics.

Management of Pain and Swelling

- Care should be taken not to allow exercise progression through pain with stress fracture.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Same as described in Phase I but progressing to more aggressive joint techniques if ROM impairment persists.

Soft Tissue Techniques

- Same as described in Phase I.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Same as described in Phase I.

Sensorimotor Exercises

- Begin with static balance exercises such as single leg stand on floor with eyes open and progress to less stable surface and eyes closed.
- Progress athlete to higher demand static balance exercise, including single leg stand on unstable surface with upper extremity challenges, including diagonal upper body movements, resisted upper extremity exercise, BodyBlade, and elastic rebounder.

Open and Closed Kinetic Chain Exercises

- Avoid any impact loading that is painful. If the athlete can perform closed kinetic chain exercises without leg pain, then these should not be restricted.

- Add multiplanar closed chain movements in Phase II, including multidirectional lunges, lunge with trunk rotation, squats with upper extremity diagonal patterns.

Techniques to Increase Muscle Strength, Power, and Endurance

- Niemuth[5] identified hip abductor muscle weakness in a group of recreational runners with lower limb overuse injuries.
- Address any muscle imbalances in the lower kinetic chain. This should be based on careful manual muscle testing and observational gait analysis.

Plyometrics

- May introduce if athlete is pain free with all ground based exercises. Begin early plyometric training (no evidence for plyometrics in treatment of stress fracture) with mini-trampoline double leg hops, double leg drop squats, and double leg decline squats. These exercises must be pain free and performed no more than three times/week on alternate days.

Functional Exercises

- Begin transition to land running with a walk-jog-run progression.
- Generally the athlete resumes running or weight-bearing training at no more than 50% of the volume that he or she was doing at the time of injury onset, although this recommendation is based on expert opinion rather than controlled trials.
- Weight-bearing activities should be limited to an exposure that does not increase symptoms.
- It is commonly recommended to increase weekly weight-bearing exposure by approximately 10% per week, although this rate of progression has not been tested in clinical trials.
- It is important that weight-bearing training be reduced or deferred if symptoms increase.

Milestones for Progression to the Next Phase

- Pain-free early plyometrics and walk-jog-run progression
- No tenderness to palpation or percussion, negative provocative maneuvers (hop test, pain on tuning fork examination, pain with fulcrum testing) on physical examination is allowed for high-risk stress fractures.

Phase III (weeks 4 to 16 or longer): Functional Training Phase

Protection

- Pneumatic air brace for weightbearing activities as needed until pain free with all activities for 1 to 2 weeks.

Management of Pain and Swelling

- Care should be taken not to allow activity progression to worsen pain with stress fracture.

Sensorimotor Exercises

- Progress athlete to dynamic balance activities (whole body movement) using jumping/hopping to and from BOSU ball, slide board movements, balance beam exercise.

Open and Closed Kinetic Chain Exercises

- Progress the challenge, intensity and speed of the multiplanar closed chain exercises introduced in Phase II.

Plyometrics

- Progress to higher level plyometric exercises including ankle hops on floor (double to single leg), depth jumps, box jumps, squat jumps, tuck jumps, and bounding.

Functional Exercises

- Continue with walk-jog-run progression

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- Completion of functional progression
- Performance of all plyometric exercises without tibial pain

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention

- Anterior mid-tibia and medial malleolus stress fracture not responding to nonsurgical care or showing signs of non-union. In high-performance and elite athletes, early surgical treatment should be considered because this may lead to a more rapid return to competition and a lower risk for recurrence.
- Assess compliance in athletes who remain symptomatic from low-risk stress fractures beyond 8 to 12 weeks of treatment. Consider evaluation or re-evaluation for nutritional insufficiencies and other causes of osteopenia.

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Pain-free running on successive days
- Athletes with low-risk stress fractures may be allowed to participate if they have full range of motion, full

strength, and can perform the demands of their sport without gait changes.
- No tenderness to palpation or percussion, negative provocative maneuvers (hop test, pain on tuning fork examination, pain with fulcrum testing) on physical examination is allowed for high-risk stress fractures.

Evidence

Arendt D, Griffiths H: The use of MR imaging in the assessment and clinical management of stress reactions of bone in high-performance athletes. *Clin Sports Med* 16:292–306, 1997.

A widely cited reference proposing a grading scale based on MRI appearance and along with prognostic and return-to-play recommendations. (Level V evidence)

Burgi AA, Gorham ED, Garland CF, et al: High serum 25-hydroxyvitamin D is associated with a low incidence of stress fractures. *J Bone Miner Res* 26(10):2371–2377, 2011.

Vitamin D levels were measured in incoming military recruits. Six hundred female recruits diagnosed with stress fracture of the tibia or fibula within the first 180 days of service were matched for age, race, and length of service and vitamin D levels compared, along with BMI and state of residence at time of entry into military service. Recruits in the highest quintile of vitamin D levels had half the risk for stress fracture. (Level IIIb evidence)

Kaeding CC, Yu JR, Wright R, et al: Management and return to play of stress fractures. *Clin J Sport Med* 15(6):442–447, 2005.

Excellent review of high- and low-risk stress fractures, treatment algorithm, and return-to-play recommendations. (Level V evidence)

Matheson GO, Clement DB, McKenzie DC, et al: Stress fractures in athletics: a study of 320 cases. *Am J Sports Med* 15:46–58, 1987.

This is one the largest early series of stress fractures in athletes. Physical findings, risk factors, prognosis, and radiographic and scintigraphic changes are discussed in this pre-MRI era study. (Level IV evidence)

Nattiv A, Loucks AB, Manore MM, et al: American College of Sports Medicine position stand. The female athlete triad. *Med Sci Sports Exerc* 39(10):1868, 2007.

The ACSM position stand reviews the current understanding of the complex interaction among exercise volume, energy availability, and current treatment recommendations. (Level IIa evidence)

Swenson EI, DeHaven KE, Sebastianelli WJ, et al: The effect of a pneumatic leg brace on return to play in athletes with tibial stress fractures. *Am J Sports Med* 25(3):322–328, 1997.

Athletes with stress fractures treated with a pneumatic leg brace returned to light activities in a median 7 days vs. 21 days in unbraced athletes in this randomized trial, and experienced symptom resolution with full activities in 21 ± 2 days in braced athletes vs. 77 ± 7 days. (Level Ib evidence)

Multiple Choice Questions

QUESTION 1. Which of the following features is not characteristic of a high-risk stress fracture?

A. High risk of fracture recurrence
B. High degree of pain
C. High risk of nonunion
D. High risk of fracture completion

QUESTION 2. Which intervention has been shown to decrease time to return to play for athletes with tibial stress fracture?

A. Vitamin D supplementation
B. Calcium supplementation
C. Pneumatic leg brace
D. High-dose nonsteroidal antiinflammatory drugs

QUESTION 3. Which of the following is not a risk factor for tibial stress fracture?

A. Leg-length inequality
B. Running on asphalt
C. Rapid training progression
D. Athletic menorrhea

QUESTION 4. Which of the following activities is not appropriate for Phase I rehabilitation?

A. Plyometrics
B. Hip abductor strengthening
C. Stretching exercises for the gastrocnemius and soleus
D. Pool running that does not exacerbate pain

Answer Key

QUESTION 1. Correct answer: **B** (see Phase I)

QUESTION 2. Correct answer: **C** (see Phase I)

QUESTION 3. Correct answer: **C** (see Phase I)

QUESTION 4. Correct answer: **A** (see Phase I)

POSTOPERATIVE REHABILITATION AFTER TREATMENT OF EXERTIONAL COMPARTMENT SYNDROMES

Dana Curtis Covey, MD, MSc, CAPT, MC USN, and Shane A. Vath, CDR, MSC USN

Introduction

- Exertional compartment syndrome is compartmental pain and swelling caused by exercise, and that is relieved with rest. There are two types:
  - *Chronic exertional compartment syndrome* (CECS) is a less emergent form in which symptoms recur with repetitive exertional activities, and is the most common type seen in athletes.
  - The second type, *acute compartment syndrome*, can also occur in athletes secondary to direct trauma or may develop from pre-existing CECS.
- The leg is the most common site of exertional compartment syndrome. In CECS, the diagnosis is usually confirmed by measuring compartment pressures before and after exercise. Fasciotomy is the definitive treatment.

Indications for Surgical Treatment

- A history and physical examination consistent with exertional compartment syndrome
- Failure of conservative treatment
- One or more of the following criteria for compartment pressure readings; with the greater the number of criteria, the higher the level of confidence[1]
  - Pre-exercise pressure 15 mmHg or greater
  - One minute post-exercise pressure 30 mmHg or greater
  - Five minute post-exercise pressure 20 mmHg or greater
- The Stryker catheter is the device most widely used for intra-compartmental pressure testing and is placed into one of four compartments (in the case of leg involvement), both pre- and postexercise

Brief Summary of Surgical Treatment

Major Surgical Steps

- Major technique steps in open compartment fasciotomy[2,3] for treatment of CECS of the leg:
  - First, have a thorough knowledge of compartmental anatomy
  - Identify the involved compartment(s) to be released
  - For an anterior or lateral compartment release, an incision is made in line with the leg midway between the tibia and fibula. The anterior intermuscular septum is identified. A horizontal fasciotomy incision is made the length of the compartment in front of the septum to release the fascia of the anterior compartment, and behind it to release the lateral compartment. Take care to avoid injury to the superficial peroneal nerve. Each involved compartment should be released completely
  - To release the superficial or deep posterior compartments, a horizontal incision is made 1 to 2 cm posterior to the posteromedial border of the tibia is made being cognizant of the location of the saphenous vein and nerve. The fascia overlying the gastrocnemius and soleus muscles (superficial posterior compartment) is divided along its length. Fasciotomy of the deep posterior compartment is next accomplished by retracting the gastrocnemius-soleus complex to expose the flexor digitorum longus in the deep posterior compartment. Its fascia should be incised along its length, and the soleus bridge should be released as well, taking care to avoid injury to the posterior tibial artery and vein.

Factors That May Affect Rehabilitation

Anesthetic

- Regional or general anesthesia

Surgical

- Open versus subcutaneous versus endoscopic fasciotomy

Other Surgical Techniques and Options

- Subcutaneous fasciotomy technique[4]
- Endoscopic technique of fascial release[5]

Before Surgery: Overview of Goals, Milestones, and Guidelines[1]

- Before surgery, conservative treatment methods for treatment of CECS can be tried. These include:
  - Reducing training intensity
  - Discontinuing the activity causing symptoms
  - A period of rest, after which exercise may slowly increase
  - Ice and nonsteroidal antiinflammatory medications (NSAIDs)
  - Orthotics to correct foot position during running
  - Avoidance of running on hard surfaces
  - Changing footwear
  - Altering running mechanics

[1] *Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

- Deep tissue massage, ultrasound, and stretching before exercise

GUIDING PRINCIPLES OF POSTOPERATIVE REHABILITATION

- Document pre- and postexercise compartment pressures.
- Release only the involved compartment(s).
- Understand the anatomy and surgical technique for each compartment.
- Ensure a complete fascial release of the involved compartment.
- Avoid neurovascular injury by adequately visualizing the fascia being incised.

Phase I (days 0 to 14): Immediate Postoperative Period

Clinical Pearl

Following compartment release patients will often experience paresthesias in the nerve distribution of the involved compartment(s) or distributions of other peripheral nerves owing to the surgical procedure and resulting lower extremity edema. Sensory and motor disturbances should be noted. Progressive improvements should occur as swelling resolves and healing progresses. Patients should be provided education regarding gradual return of nerve function and encouraged to inform their treating surgeon if a gradual improvement does not occur or symptoms progressively increase.

Goals

- Minimize and reduce postoperative pain, inflammation, and swelling of the involved lower extremity to limit scar formation.
- Educate athlete on importance of RICE (rest, ice, compression, elevation) and gentle motion respecting pain to reduce swelling and pain.
- Provide progressive stress to soft tissue to encourage functional scar formation that does not restrict compartment(s) or otherwise limit function.

Protection

- Crutches and weight bearing as tolerated.
- Avoid activities that increase swelling, such as: prolonged positions/activities with limb in dependent position, heat, restrictive clothing or poorly applied wraps over or proximal to swelling.

Management of Pain and Swelling

- Oral pain medications
- Therapeutic modalities for pain and swelling
- Cryotherapy to aid in reducing pain, inflammation, and swelling
- Compression to involved extremity. Tubular compression doubled over the foot and ankle increases likelihood of proper application. Simplicity of application improves compliance for daily use.
- Patient education: Use pillows or bolsters to elevate leg above the level of the heart to reduce pressure and swelling. Perform ankle pumps to encourage venous return.
- Retrograde massage may be employed intensity and duration appropriate to wound healing if swelling persists despite performing other management instructions and techniques.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- ROM: Precautions: "respect pain." Provide patient guidance on intelligent progression: range of motion, repetitions, sets, and frequency to regain normal hip, knee, ankle, and foot motion. Activity extremes can result in prolonged pain and swelling. Appropriately caution patient regarding extremes of inactivity/activity and association with prolonged pain and swelling. This can lead to over scarring, which may reduce functional outcome.
- PROM: Manual range of motion of ankle, knee, and hip can be performed early in rehabilitation but patient progression to active motion is encouraged. This enables more frequent independent mobilization.

Soft Tissue Techniques

- Inspect incision site. After wound is well healed following staple/suture removal gentle desensitization and mobilization techniques consistent with wound healing can be initiated to reduce pain, promote mobility, and reduce adhesions.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Seated calf towel stretch with knee extended and knee flexed.
- Seated → quadruped toe down stretch with addition of inversion and eversion force as tolerated (Figure 36-3).
- Seated heel slide with foot flat to encourage ankle dorsiflexion/plantarflexion and knee/hip motion.

Other Therapeutic Exercises

- Perform upper body low intensity cardiovascular activities such as upper body ergometer (UBE) or resistance training. Consider duration of time spent with legs in dependent position. Adjust based on athlete's response.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Heel slides
- Four-way hip SLR on plinth
- Supine double → single leg hip bridging

FIGURE 36-3. Quadruped toe-down stretch.

- Ankle dorsiflexion/plantarflexion supine with leg elevated
- Ankle alphabet
- Progress to light four-way ankle resistance exercises as tolerated.

Sensorimotor Exercises

- Progress crutch ambulation weight bearing as tolerated while encouraging normal gait. Use pain, swelling and function to guide progression. Wean from crutch use for household → community ambulation.
- Weight shifting: Standing on involved leg with support as needed keep foot flat step forward/backward and side/side.

Open and Closed Kinetic Chain Exercises

- As listed in the preceding

Techniques to Increase Muscle Strength, Power, and Endurance

- Main goal during this phase is to reduce swelling, pain, and promote healing while minimizing negative effects of reduced activity/mobility.

Functional Exercises

- Gait training to encourage normal gait pattern with increased tolerance for weight bearing and decreased pain. Encourage WBAT while minimizing reproduction of pain.

Milestones for Progression to the Next Phase

- Minimal soft tissue swelling of involved extremity.
- Demonstrate ability to independently ambulate100 feet with minimal gait deviations and 2/10 or less pain.
- Demonstrate ability to ambulate at least 75% weight bearing with crutches community distances (2000 feet) without pain.

Phase II (postoperative weeks 2 to 4)

Clinical Pearl

Response following surgical compartment release is highly variable. Ensure that the athlete's subjective input and objective findings correlate before higher level progression. Rehabilitation should match clinical presentation, emphasizing intelligent progression from lower to higher load activities with continued assessment and adjustment based on response. Use caution when returning to higher load activities: hill walking, ambulation in shoes with elevated heel, eccentric or plyometric loading of involved compartment(s), and especially running or other activity that produced the preoperative symptoms. These activities may cause a drastic increase in limb pain and swelling, resulting in extended healing and delayed return to sports activities. Ensure that the athlete is educated to improve compliance and limit inappropriate independent progression of activities. Avoid reproducing preoperative symptoms during rehabilitation.

Goals

- Unassisted ambulation without gait deviations for ¼ mile or 5 minutes
- Full pain-free range of motion and strength of foot and ankle

TIMELINE 36-3: **Postsurgical Rehabilitation After Surgical Treatment of Exertional Compartment Syndromes**

PHASE I (postoperative weeks 0 to 2)	PHASE II (postoperative weeks 2 to 4)
• Crutches, WBAT • Gait training • Inspect incision • PT modalities • ROM: Hip, knee, ankle, foot • Stretch: gastroc/soleus/toe down • RICE • Patient education	• Progress to unassisted ambulation • PT modalities: cryotherapy • Scar/soft tissue mobilization • Bicycle → elliptical • Walking program • AROM • Initiate strengthening • Active functional exercise • Wobble board • Early sport-specific training

- Scar healed with good mobility and minimum discomfort
- Continue to manage swelling, minimize scar formation, and maximize progressive return to function.
- Appropriately stress soft tissue to ensure functional scar formation that does not restrict compartment(s) or limit function.

Protection

- Crutches/cane should only be used for walking if the individual is experiencing pain or swelling. Encourage reduced use of assistive devices if minimal pain, swelling, and good function.

Management of Pain and Swelling

- Oral pain medications are continued as needed for pain and swelling.
- Therapeutic modalities for pain and inflammation are continued as needed.
- Cryotherapy with compression is continued to aid in reducing pain and swelling, especially following exercise/activity.
- Tubular compression is continued as needed to manage swelling of the extremity.
- Patient education: As swelling resolves, increase time spent with the extremity in dependent positions. Use elevation and ankle pumps when required to reduce swelling with decreasing frequency.
- Retrograde massage may be employed intensity and duration appropriate to wound healing if swelling persists despite performing other management instructions and techniques.
- If swelling continues, inquire regarding daily activities/exercise and adjust as appropriate.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- ROM: Precautions: "respect pain." Continue guiding the athlete on intelligent progression: range of motion, repetitions, sets, and frequency to regain full pain free ankle and foot motion. Progress activity/exercise level but continue to caution the athlete regarding extremes of inactivity/activity and association with prolonged pain and swelling. During this phase activity extremes can still increase pain and swelling and produce overscarring, reducing functional outcome. Progress loads from low to high with increasing speed and power: isometric, concentric, eccentric, plyometric.
- PROM: This should only be performed if the patient lacks full motion. Active motion and exercise encourages more functional and higher loads to tissues.

Soft Tissue Techniques

- Continue using scar desensitization and mobilization techniques as needed consistent with wound healing to promote mobility and reduce adhesions.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Pre-exercise:
  - Active stretching: Standing on involved extremity with foot flat step forward/backward at angles and side to side stepping in front/behind opposite leg
- Post-exercise:
  - Standing calf stretch, increasing slant board angle with knee extended and knee flexed
  - Quadruped toe down stretch with increasing downward pressure and angle of inversion and eversion as tolerated (see Figure 36-3)

Other Therapeutic Exercises

- Increase intensity and duration of upper body cardiovascular activities such as upper body ergometer or resistance training. Continue resistance training specific to sport and transition to lower extremity cardiovascular training based on athlete response to more intense activity with legs in dependent position.
- Short bouts of low intensity low resistance stationary bicycle can be utilized to encourage self-mobilization of involved lower extremity. Following anterior or lateral compartment, release progression to toe clip use based on symptoms. Increase duration, intensity, and resistance of stationary bicycle to provide progressive stress to soft tissue, based on athlete response.
- Progressively add elliptical trainer.
- When nonpainful with stationary bicycle/elliptical and unassisted community walking, begin walking program (Box 36-2) documenting: pace, distance, and the athlete's response (pain, swelling). Progress the program based on the athlete's response. The program can be

TIMELINE 33-3 Postsurgical Rehabilitation After Surgical Treatment of Exertional Compartment Syndromes (Continued)

PHASE III (postoperative weeks 4 to 6)	PHASE IV (postoperative weeks 6 to 10)	PHASE V (postoperative weeks 10 to 12)
• Normal unassisted ambulation • PT modalities as needed • Scar/soft tissue mobilizations as needed • Elliptical/bike as desired • Active/passive stretching • Walking program → walk/run program • Progress strengthening • Active functional exercise: increase speed/power • Plyometric shuttle exercises • Sport-specific drills • Cryotherapy following exercise	• PT modalities as needed • Elliptical/bike for high-intensity training • Active/passive stretching • Walking program → walk/run progression • Strengthening as needed • Plyometric shuttle • Sport-specific drills • Sprint progression	• Continue run progression • Manage as needed

BOX 36-2 Progressive Walking/ Running Program*

Step 1: Walk on treadmill, progressing up to 20 minutes at a comfortable pace
Step 2: Walk for 5 minutes
Then jog for 1 minute, walk for 4 minutes × three cycles (total of 15 minutes)
Walk for 5 minutes at a comfortable pace.
Step 3: Walk for 5 minutes
Then jog for 2 minutes, walk for 3 minutes × three cycles (total of 15 minutes)
Walk for 5 minutes at a comfortable pace.
Step 4: Walk for 5 minutes
Then jog for 3 minutes, walk for 2 minutes × three cycles (total of 15 minutes)
Walk for 5 minutes at a comfortable pace.
Step 5: Walk for 5 minutes
Then jog for 4 minutes, walk for 1 minute × three cycles (total of 15 minutes)
Walk for 5 minutes at a comfortable pace.
Step 6: Walk for 5 minutes
Jog for 15 minutes
Walk for 5 minutes
Step 7: Walk for 5 minutes
Jog for 20 minutes
Walk for 5 minutes
Step 8: Warm up
Progress your running distance and intensity as tolerated
Cool down

*This program is to be performed three times per week. *Do not* walk or run past the point of "pain" (although discomfort or soreness is OK).

progressed rapidly if the athlete is asymptomatic. Stop the program if preoperative symptoms are reproduced and return to bicycle/elliptical.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Ankle Isolator: Dorsiflexion, plantarflexion, inversion, eversion
- Ankle resistance band exercises: Dorsiflexion, plantarflexion, inversion, eversion

Sensorimotor Exercises

- Weight shifting: Standing on involved/uninvolved leg: supported → unsupported on a flat surface → elevated surface keep foot flat step forward/backward and side/side. (An elevated surface promotes increased ankle motion and loads.)
- Perform exercises to begin loading in a more functional manner. Increase range of motion, distance, speed, and power with exercises over time.
  - High knees with hip/knee flexion with ankle dorsiflexion; hip/knee extension with ankle plantarflexion
  - Side stepping with squat add resistance band as able
  - Grapevine stepping
  - Side stepping with squat → hop.
  - Walking lunges
- Seated → standing balance/wobble board supported → unsupported: clockwise/counterclockwise; forward/backward; side/side; angles

Techniques to Increase Muscle Strength, Power, and Endurance

- Per preceding, increasing sets, reps, speed, power based on symptoms

Neuromuscular Dynamic Stability Exercises

- Can begin single leg rebounder on flat stable surface → soft or uneven surfaces as desired

Plyometrics

- Plyometric shuttle: Begin double leg jumping and progress to single leg as able.

Functional Exercises

- Per the preceding

Sport-Specific Exercises

- Once scar is healed and there are minimal symptoms, the athlete can begin sport-specific training with the exception of running, impact activities, or other activities that produced symptoms before surgical release.
- Pool exercises: Once incision well healed can begin swimming, pool walking/running in deep → shallow water.

Milestones for Progression to the Next Phase

- No soft tissue swelling or mild intermittent swelling of involved extremity following exercise. Swelling should resolve prior to the next exercise session.
- Demonstrate ability to ambulate at least ¼ mile or 5 minutes with normal gait and 2/10 or less pain.
- Scar healed with good mobility, minimal tenderness causing no limitation of foot and ankle motion.

Phase III (postoperative weeks 4 to 6)

Clinical Pearl

Resolution of pain and swelling and return to function following surgical release is variable. Progress athletes to eccentric, plyometric, impact, sport-specific activities, and running in an intelligent manner based on subjective report, objective findings, and response to exercise. The athlete should stop activities as soon as preoperative symptoms begin or if they produce prolonged postexercise pain greater than about 2 hours. As healing progresses, a gradual or rapid increase in exercise tolerance with

decreasing symptoms of pain and swelling during or postexercise is expected. If the patient experiences prolonged pain following exercise and/or function is not improving, then the athlete's exercise program should be evaluated to determine aggravating activity(ies) and adjusted appropriately.

Goals

- Walk 12 minutes or more at moderate pace with 2/10 or less pain.
- Appropriately stress soft tissue to ensure functional scar formation that does not restrict compartment(s) or limit function.
- Perform sport-specific training, progressively adding jumping, lower extremity plyometrics, and progressive running activities.
- Progress to walk run program when able to walk 20 minutes with 2/10 or less leg pain that resolves within about 2 hours postexercise (see Box 36-2).

Management of Pain and Swelling

- Continue previous treatment methods as needed based on athlete's symptoms and response.
- Cryotherapy should be performed following exercise sessions to control pain and swelling.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- As clinically indicated

Soft Tissue Techniques

- Only perform scar desensitization and mobilization techniques if scar is sensitive, painful, adhesed, or limits mobility or function. Transverse friction massage may be used to improve soft tissue mobility/extensibility of the leg.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Continue active stretching before exercise as desired and static stretching following exercise
  - Pre-exercise as desired:
    - Active stretching on elevated surface: standing on involved/uninvolved extremity with foot flat step forward/backward at angles and side/side stepping in front/behind opposite leg. Standing calf stretch increasing slant board angle with knee extended and knee flexed.
  - Post-exercise:
    - Standing calf stretch increasing slant board angle with knee extended and knee flexed.
    - Toe down stretch on hands and knees increasing downward pressure and inversion/eversion force.

Other Therapeutic Exercises

- Continue resistance training specific to sport and increase lower extremity cardiovascular training based on athlete's response.
- Perform stationary cycling if appropriate to sport or if athlete's desires higher intensity cardiovascular training. Increase duration, intensity, and resistance of stationary bicycle as desired.
- Continue elliptical trainer based on athlete desire and ability to tolerate progression to walk/run program.
- When able to progress to 20 minutes of continued walking with 2/10 pain or less and minimum swelling or duration of post exercise pain begin progression to walk/run program. Document: pace, distance and the athlete's response (pain intensity/duration, swelling). Adjust or stop program based on response.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Continue as needed.
- Ankle Isolator may be continued as needed, progress weight, reps and sets: dorsiflexion, plantarflexion, inversion, eversion.
- Ankle resistance band exercises may be continued as needed, progress weight, reps, sets: dorsiflexion, plantarflexion, inversion, eversion.

Sensorimotor Exercises

- Weight shifting may be continued as needed.
- Continue functional exercises as needed increasing range of motion, distance, speed, power with exercises over time.
  - High knees with hip/knee flexion with ankle dorsiflexion; hip/knee extension with ankle plantarflexion
  - Side stepping with squat add resistance band as able
  - Grapevine stepping
  - Side stepping with squat → hop
  - Walking lunges
  - Ladder drills specific to sport
- Balance/wobble board may be continued as needed, add weight as able: standing minimal support clockwise/counterclockwise; forward/back; side/side; angles.

Open and Closed Kinetic Chain Exercises

- Exercises listed in the preceding

Neuromuscular Dynamic Stability Exercises

- Single leg rebounder on flat stable surface → soft surfaces as desired.

Plyometrics

- Plyometric shuttle progress to single leg jumping with higher resistance and greater reps.
- Perform sport specific drills increasing duration and intensity as appropriate without reproducing leg pain

or producing prolonged post exercise pain for greater than 2 hours.

Sport-Specific Exercises

- Begin plyometrics and sprinting without increasing pain or swelling. Use caution with return to contact/collision activities due to potential for blunt injury or re-aggravation of soft tissue.

Milestones for Progression to the Next Phase

- Walking 12 minutes or more at moderate to fast pace with 2/10 or less pain.

Phase IV (postoperative weeks 6 to 10)

Clinical Pearl

Return to running should be gradual and progressive in nature to provide gradual stress to lower extremities without increased pain or reduced function owing to irritation of legs or other overuse injury. The program should be performed every other day so symptoms can be assessed on rest days. Desire gradual increase in tolerance to exercise and running with reducing symptoms. If pain or symptoms are increasing and function declining, then the athlete should be rested until there is a return to baseline. Athletes should cease running at the onset of preoperative symptoms. Endurance runners are typically eager to return to running and often ignore symptoms. Supervised run progression on a treadmill or indoors can help mitigate the urge to run despite symptom reproduction.

Goals

- Progress to walk run program when able to walk 20 minutes with 2/10 or less leg pain that resolves within about 2 hours postexercise (see Box 36-2).
- Running distances as tolerated without reproduction of preoperative symptoms or swelling with minor postexercise pain that resolves within about 2 hours.

Management of Pain and Swelling

- Cryotherapy can be performed following exercise sessions to reduce any pain or swelling.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- As clinically indicated

Soft Tissue Techniques

- Perform previous treatment as indicated.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Perform active warm up before running/exercise as desired.
- Following exercise perform static stretching
  - Standing calf stretch with forefoot elevated with knee extended and knee flexed.
    - Toe down stretch on hands and knees increasing downward pressure and inversion/eversion force (Figure 36-3).

Other Therapeutic Exercises

- Continue previous phase exercises/progression.
- Continue resistance training specific to sport and increase lower extremity cardiovascular training based on athlete's response.
- Perform stationary cycling if appropriate to sport or if athlete's desires higher intensity cardiovascular training while progressing back to running. Increase duration, intensity, and resistance of stationary bicycle as desired.
- Continue elliptical trainer based on athlete desire and ability to tolerate progression to walk/run program.
- Progress to walk/run program (see Box 36-2) when able to walk 20 minutes with 2/10 or less leg pain that resolves within about 2 hours postexercise and athlete has minimal swelling. Document: pace, distance and the athlete's response (pain: intensity/duration, swelling). Adjust program based on response.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Perform exercises from previous phase as needed. Main focus is to return to running and sport-specific activity.

Sensorimotor Exercises

- Perform as needed.

Plyometrics

- Continue plyometric shuttle progression as needed.
- Continue to progress sport specific drills increasing duration and intensity as appropriate without reproducing leg pain.

Sport-Specific Exercises

- Continue plyometric and sprinting progression being aware of any increase in pain or swelling. Progress to contact/collision activities.

Evidence

Detmer DE, Sharpe K, Sufit RL, et al: Chronic compartment syndrome: diagnosis, management and outcomes. *Am J Sports Med* 13(3):162–170, 1985.

This is a case series of 100 patients with chronic exertional compartment syndrome who received fasciotomy for

treatment. At follow-up, 90% of patients had resolution or significant improvement of their symptoms at a median of 4.5 months postoperatively. Operative and postoperative complications occurred in 11 patients.

Houglum P: Soft tissue healing and its impact on rehabilitation. *J Sport Rehabil* 1:19–39, 1992.

This is an overview of the chemical and cellular activity involved in soft tissue healing, with emphasis on aspects that can be affected by rehabilitation. Guidelines are presented for a rehabilitation program based on the physiological effects of the healing process. A rehabilitation program must be carefully coordinated with the timing of tissue healing and designed in a logical sequence to permit successful rehabilitation of the injured athlete.

Mouhsine E, Garafalo R, Moretti B, et al: Two minimal incision fasciotomy for chronic exertional compartment syndrome of the lower leg. *Knee Surg Sports Traumatol Arthrosc* 14:1093–1097, 2006.

This study reports results following a minimal double incision fasciotomy for CECS. Eighteen athletes with CECS of the leg underwent a minimal double incision fascial release a mean of 4 months after onset of symptoms. At 2-year follow-up, all had resumed preinjury levels athletic activity. Complications occurred in 2 of the 11 patients who underwent to bilateral fasciotomy in that they had a sensation of leg weakness for an average period of 3 months.

Mubarak SJ, Owen CA: Double-incision fasciotomy technique of the leg for decompression in compartment syndrome. *J Bone Joint Surg Am* 59:184, 1977.

This paper describes the surgical anatomy of the compartments of the leg and describes a technique using anterolateral and posteromedial incisions for access to all four compartments of the leg for fascial release.

Pedowitz RA, Hargens AR, Mubarak SJ, et al: Modified criteria for the objective diagnosis of chronic compartment syndrome of the leg. *Am J Sports Med* 18(1):35–40, 1990.

This is a retrospective study of 131 patients who were evaluated for possible chronic exertional compartment syndrome (CECS). Forty-five were diagnosed as having CECS. Given an appropriate history and physical examination, one or more of the following intramuscular pressure criteria were diagnostic of CECS: a pre-exercise pressure 15 mmHg or greater; a 1-minute postexercise pressure 30 mmHg or greater; a 5-minute postexercise pressure 20 mmHg or greater.

Schubert A: Exertional compartment syndrome: review of the literature and proposed rehabilitation guidelines following surgical release. *Int J Sports Phys Ther* 6(2):126–141, 2011.

This article summarizes literature regarding CECS and proposes scientifically based guidelines for rehabilitation following compartment release. A literature search was performed and there were no specific guidelines following surgical for rehabilitation after compartment release for lower extremity CECS. Guidelines are proposed for rehabilitation following compartment release with rationale based on tissue healing, muscle loading, and scar tissue formation. (Level X evidence)

Verleisdonk EJ, Schmitz RF, van der Werken C: Long-term results of fasciotomy of the anterior compartment in patients with exercise-induced pain in the lower leg. *Int J Sports Med* 25(3):224–229, 2004.

This prospective study describes the results of fasciotomy in patients with exercise-induced pain in the lower leg from suspected chronic exertional compartment syndrome. Tissue measurements were performed in 114 patients. In 56 patients (106 compartments) increased tissue pressure was found (greater than 50 mmHg measured immediately after exercise, or greater than 30 mmHg if the pressure before exercise greater than 20 mmHg, or if the pressure 5 minutes after exercise is still greater than 30 mmHg). Two years postoperatively, patients were evaluated by questionnaire and 87% had significant reduction in symptoms. Eighteen patients not found to have increased tissue pressure also participated. In these patients, a fasciotomy was performed based on typical history, despite normal or slightly increased intramuscular pressures, and 12 patients (24 compartments) were asymptomatic after surgery. Fasciotomy in patients with CECS in the leg resulted in marked symptom reduction in most of patients.

Wittstein J, Moorman CT, Levin LS: Endoscopic compartment release for chronic exertional compartment syndrome. *Am J Sports Med* 38(8):1661–1666, 2010.

This is a case series of nine patients (14 legs) with chronic exertional compartment syndrome who underwent endoscopic compartment release with the assistance of a balloon dissector. Eight of nine patients were able to return to their preoperative athletic activities. The only complications were hematomas that resolved in two patients.

Multiple Choice Questions

QUESTION 1. What is the main goal immediately following surgical compartment release?

A. Protect healing fascia
B. Ambulate without crutches
C. Manage pain and swelling to limit scar formation
D. Increase mobility of incision site

QUESTION 2. Patients' physical response following surgical compartment release is best described as:

A. Highly consistent
B. Highly variable
C. Immediate improvement
D. Rarely experience swelling

QUESTION 3. After the athlete has returned to running, the running should be progressed when the athlete has:

A. Reduced exercise tolerance with increased pain
B. Pain that limits ability to increase exercise
C. Constant pain that does not limit exercise
D. Increased tolerance to exercise with reduced pain

QUESTION 4. A running program should be initiated:

A. 6 weeks following surgery
B. When the incision site is healed
C. When patient can tolerate walking 20 minutes with minimal pain/swelling
D. 12 weeks following surgery

Answer Key

QUESTION 1. Correct answer: **C** (see Week 0 to 2)

QUESTION 2. Correct answer: **B** (see Week 2 to 4)

QUESTION 3. Correct answer: **D** (see Week 6 to 10)

QUESTION 4. Correct answer: **C** (see Week 6 to 10)

BEYOND BASIC REHABILITATION: RETURN TO RUNNING AFTER STRESS FRACTURE OF THE TIBIA

Kari Sturtevant, DPT, OCS, Danielle Cooper, PTS, NSCA-CPT, and Timothy S. Mologne, MD

Introduction

ASPECTS OF RUNNING THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- Hip strength and lower limb control with closed chain activities
- Correction of faulty running biomechanics
- Graduated return to running program

Incidence

- Running has become increasingly popular in recent years. It is a quick, practical, low cost form of exercise leading to rapid gains in cardiovascular fitness.
- Although the positive effects of running are numerous, participants are at high risk of running-related overuse injuries.
- Epidemiologic studies of runners report that up to 79% of runners incur an overuse injury within any given year.[1,2] Of novice runners, 20% to 34% become injured within the first 13 weeks of training.[3]
- The most common site of running related injury is the knee, followed by the lower leg, foot, and upper leg.[2]
- According to Bennell et al.[1] stress fractures occur in 21% of elite track and field athletes.
- The overall incidence of stress fracture is 0.70 per 1000 hours of training. The tibial is the most common site for stress fractures in runners, accounting for 46% of all stress fractures. The distance running population is most likely to experience stress fractures, accounting for 31.6% of total fractures.[1]
- During a 12-month period, 60% of track and field athletes who sustained a fracture had a previous history of this diagnosis This high recurrence rate suggests a continuation of risk factors such as: "abnormal biomechanics, excessive training, and low bone density."[1]

Risk Factors for Stress Fracture

- The multifactorial nature of running related injuries and high recurrence rate poses a challenge for effective rehabilitation and safe return to sport.
- It is generally understood that running-related injuries are a result of an amalgamation of intrinsic and extrinsic factors that surpass a runner's individual capacity to withstand them. Established risk factors include[4,5]:
  - Weekly mileage or intensity (training errors)
  - Faulty biomechanics
  - Strength deficits
  - History of previous injury
- Those that increase their mileage rapidly or train more than 40 miles per week are approximately three times more likely to sustain injury.[1]
- A significant correlation between previous running injury and risk of future injury have been reported.[1,2]

Training Errors

- Hreljac et al.[6] reported that up to 60% of running related injuries are a result of training errors.
- A clear mechanisms of overuse injury includes the abrupt increase in physical activity, which may be a function of the type of load applied, its peak magnitude, loading rate and/or the total doseage.[7]
- Mechanical loading is associated with microdamage of the bone.[7]
  - When stressed below the threshold of injury with adequate time to rest between sessions, bone remodels and adapts, typically resulting in greater ability to bear stress without injury.[6]

- If the body cannot successfully repair this microdamage, it will accumulate and ultimately result in fracture of the bone.[8]
- The periosteum of the bone does not mature until about 20 days after the remodeling process begins, thus leaving the bone temporarily weakened during this time.[9] This period is known as the "weak third week," or the third week after the onset of a new or increased activity.[9]
  - Continued stress applied to remodeling bone during this time may lead to accelerated breakdown of the cortex, thus it is at this time that a stress fracture is most likely to develop.[10]

Biomechanics

- In a prospective study, Davis et al. concluded that runners with higher peak positive acceleration of the tibia and higher vertical ground reaction forces were at greater risk of developing a tibial stress fracture.[11]
- Milner et al. found that female runners with a history of tibial stress fracture demonstrated greater instantaneous and average vertical loading rates compared with healthy controls.[7] Authors concluded that tibial stress fractures may be most related to loading rates.[7]
- In a systematic review of the literature on the relationship between the history of tibial stress fracture and ground reaction forces and loading rate, Zadpoor et al. concluded that the magnitude of ground reaction forces was not significantly different between the stress fracture group and controls.[7] However, the vertical loading rate (average and instantaneous) of the two groups was significantly different.[12]
- Increased peak rearfoot eversion and peak hip adduction may also be risk factors for tibial stress fracture.[13] Increased hip adduction and internal rotation in single limb stance forces the knee joint center to migrate medially relative to the foot resulting in dynamic knee valgus, an increase in tibial internal rotation and increased foot pronation.
  - Increased dynamic valgus changes the magnitude and direction of forces throughout the lower limb during closed chain tasks and increases the risk of lower limb stress fracture.

Strength and Endurance

- Niemuth et al.[14] studied hip strength of 30 injured recreational runners compared with 30 uninjured recreational runners. They concluded that the injured lower limb demonstrated significantly weaker hip abductors compared with the contralateral limb. Hip external rotators on the injured side were weaker than the uninjured side, but the difference was not statistically significant. Hip muscle strength of the control group was similar to hip muscle strength of the uninjured limb of the injured athletes. These results suggest a relationship between hip muscle weakness and overuse injuries in the recreational runner.
- Local muscle fatigue is known to influence loading rate of impact during running; Christina et al.[15] found that the loading rate of impact peak force was higher in post-fatigue runs compared to pre-fatigue runs. Thus, building endurance should be an important component of rehabilitation after lower leg stress injury.

Literature

- Stress fractures can be classified into low-risk and high-risk stress fractures.
- The most common type of tibial stress fractures occurring in runners is a low-risk posteromedial cortex (compression side) stress fracture, a low-risk fracture.[16]
- A less common type of stress fracture is the longitudinal stress fracture, also a low-risk stress fracture.[16]
  - Following a low-risk tibial stress fracture, runners ought to refrain from running and impact exercise until symptoms resolve—typically 6 to 8 weeks.
- Fractures occurring on the anterior or tension side of the tibial shaft are considered high-risk fractures. These have a propensity to delayed and nonunion fractures, thus internal fixation is frequently warranted.[16]
- The timelines in this section are based on return to running following a low-risk fracture. The same principles apply for high-risk fractures, although typical return to sports is at 4 months.[17]

Phase I (weeks 1 to 6): Advanced Strength and Conditioning Programs

- Rehabilitation can commence shortly after diagnosis of stress fracture.
- During this time frame, the athlete is at risk of significant decreases of cardiovascular and muscular function. It is recommended that he or she continues aerobic exercise with the use of modalities that off-load the lower limbs such as deep-water running, swimming, bicycling and even antigravity treadmill training.
  - A study by Liem et al.[18] suggests parameters for deep water running and antigravity treadmill training and provides sample workouts.
  - With antigravity treadmill training, the transition to land running can typically occur more quickly because the runner already has been acclimating to lower limb loading.
    - The initial attempt at land running should not occur until the runner has reached approximately 85% to 90% BW with antigravity treadmill training.[18]
- Muscle strength and endurance can be maintained and improved with trunk stabilization exercises and resistance training.
- Phase I focuses on correction of muscle imbalances, increasing muscular endurance and obtaining good lower limb control with closed chain, low-impact tasks.
- Progression beyond low impact activities occurs in Phase II at 6 to 8 weeks.

Neuromuscular Control/Strength

- A treatment program is progressed in a systematic manner from isolated muscle recruitment and

neuromuscular control to endurance, functional training, and return to running is most logical.

- Much of the existing evidence for strength training stems from research demonstrating greater weakness in injured runners compared with noninjured controls.[19]
  - Resistance exercises for the proximal hip girdle and lower limbs are incorporated with the goal of strength development and improvement in bone mineral density.[18]
  - Proximal hip and trunk strength is necessary for control of distal segments during closed chain activities. Therefore it is important to continue with strengthening and neuromuscular control exercises until the resolution of faulty biomechanics (as opposed to symptom resolution solely) to decrease risk of future injury.
- Factors such as poor neuromuscular control and lower limb proprioception have also been shown to contribute to faulty lower limb biomechanics.
  - A treatment program aimed at strengthening the weak muscles and neuromuscular re-education to control the pelvis and femur in the frontal and transverse planes thus play an important role in rehabilitation.
  - Because dynamic hip stability cannot exist without stability of the pelvis, exercise programs aimed at rehabilitation of the lower limb need to address dynamic trunk stability with a well-rounded core stabilization program.
  - Physical therapy treatment for rehabilitation of lower limb muscle imbalances need to address isolated muscle recruitment/strengthening as well as neuromuscular control.
- Strength training has also been shown to improve factors associated with running performance, such as running economy, which is how well an athlete uses oxygen at a particular running velocity.[20]

The gluteus medius and gluteus maximus play strategic roles in the control of the lower limb during running. Strengthening of these muscles has demonstrated improvement in these common running overuse injuries.[21]

- Key exercises for isolating and strengthening the gluteal musculature include:
  - Clam with Thera-Band (Figure 36-4)
    - Place Thera-Band around thighs just proximal to knees.
    - Lie on side with knees bent approximately 60° with shoulders, hips, and feet in line.
    - Without rolling backward, lift top knee while pivoting on heels.
    - Perform three sets of 10-20.
  - Bridge with leg extension (Figure 36-5).
    - Lie on back with arms above head and knees bent as in Figure 36-5.

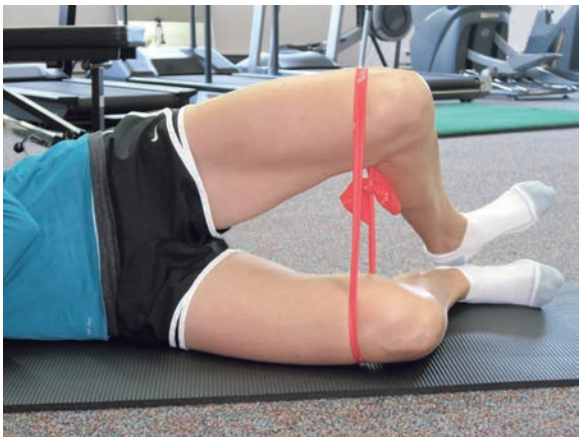

FIGURE 36-4. Clam exercise with Thera-Band resistance.

FIGURE 36-5. Bridge with leg extension. Maintain level hips by exaggerating gluteus maximus contraction in stationary leg before leg extension.

TIMELINE 36-4: **Return to Running After Stress Fracture of the Tibia**

PHASE I (weeks 1 to 6)	PHASE II (week 6) Successful Return to Running

• Aerobic exercise (pool running, swimming, bicycle)
• Strengthening of gluteus maximus, gluteus medius, and core musculature
• Neuromuscular control to eliminate the dynamic valgus tendencies
• Normalize lower extremity flexibility
• General strength training
• Patient education regarding factors leading to stress fracture and how to avoid same mistake in the future
• Criteria to progress to next phase:
  • Exemplary lower extremity control with all closed chain exercises used in Phase I
  • No pain with exercises
	• Aerobic exercise (pool running, swimming, bicycle)
	• Continue with Phase I strength and neuromuscular control exercises
	• Begin plyometrics with focus on lower extremity control and soft landing
	• Running gait retraining
	• Gradual increase of running mileage
	• Patient education regarding training programs and risk of future injury

- Lift hips off ground so that trunk and thighs are in a straight line.
- Exaggerate hip extensor contraction in stabilizing limb, extend opposite knee in a controlled manner, flex knee back to original position.
- Alternate sides.
- Perform two to three sets to fatigue or form failure.

- Side walk with Thera-Band[22] (Figure 36-6).
  - Place Thera-Band loop around ankles.
  - In a squatted position, step sideways across room, repeat the opposite direction.
  - Avoid lateral trunk movement.
  - Exaggerating a hip flexed position will best recruit the gluteus maximus.
  - Perform to fatigue or form failure.
- Single leg sit to stand[22] (Figure 36-7).
  - Find a surface that is mid-thigh height.
  - Step forward with one leg 6 to 8 inches.
  - Balance on that leg, squat down exaggerating hip flexion to lightly tap lower buttock on surface. (If you have pockets, aim to tap the bottom of the pocket on the surface.)
  - Return to upright position.
  - Exaggerating hip flexion best recruits gluteal muscles.
  - Focus on good foot and knee control.
  - Perform two to three sets of 10-20.
- A systematic approach to lower limb neuromuscular control includes an exercise progression focusing on proper alignment of the lower limbs: foot pointed forward, arch maintained, patella facing forward and hips level. The criterion for progression to more difficult exercises is proper technique with more simple exercises. The exercise progression includes:
  - Single leg stance
  - Single leg mini squat
  - Single leg side step down

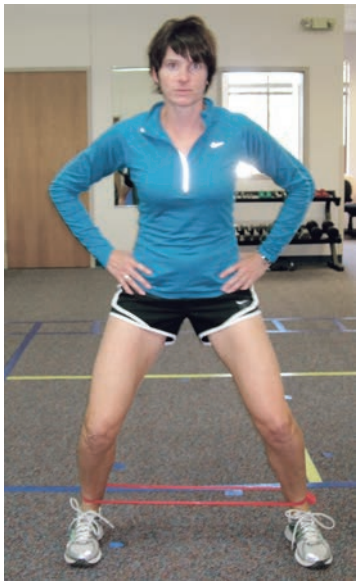

FIGURE 36-6. Thera-Band side stepping exercise. Maintain squatted position, feet pointed forward, knees pointed forward or slightly out. Perform approximately 15' one direction, and then back the other direction. Continue to fatigue.

FIGURE 36-7. Single leg sit to stand for gluteus medius and maximus strengthening and lower extremity control: Stand on one foot, 6 to 8 inches away from a surface that is mid-thigh height. Slowly squat down and reach back with hips to lightly tap the surface and stand back up. Maintain foot forward, knee forward position. Perform three sets of 10.

  - Single leg balance on uneven surfaces (add perturbations and/or ball toss to increase challenge)
- Address flexibility and ROM deficits found in evaluation in Phase I.
  - Manual therapy techniques and flexibility training should be directed at addressing deficits in range of motion and soft tissue extensibility; this is important because these limitations impart greater stress to adjacent bones.
  - At initial contact during the running gait cycle, hip flexion, knee flexion, ankle dorsiflexion, and subtalar pronation help dissipate forces and keep the center of mass low.[23]
    - Restrictions in the soft tissue that influences these joints can limit the lower limb's ability to accommodate ground reaction forces.
    - Postural muscles such as the gastroc-soleus complex (primarily soleus), rectus femoris, iliopsoas, tensor fascia lata, hamstrings, short thigh adductors, quadratus lumborum, piriformis, and sartorius, are commonly tight in runners;[24] however, each runner presents with unique impairments and a treatment plan that is tailored the individual's needs should be developed.
    - The gastroc-soleus complex is especially important when considering tibial stress fractures. A tight and shortened gastroc-soleus complex can lead to increased traction on the tibial cortex, which can result in medial tibial stress syndrome.[24] If repetitive traction persists, a stress fracture may subsequently develop.

Periodization

- Linear

Program Design/Performance Training Program

- Repetitions: 8 to 15
- Sets: two to three
- Rest interval: 60 to 90 seconds
- Intensity: 40% to 60%
- Training frequency: Strength three to four times per week, neuromuscular control daily

Phase II (weeks 6 until return to running): Sport-Specific Training

- Continue to focus on mastering neuromuscular control, strength and endurance of the hip and core musculature, as well as initiation of gait retraining.
- Plyometric exercises and Olympic lifts are introduced in this phase because these modes of training develop the runner's series elastic component (SEC). The SEC uses potential energy, producing the same force with less energy demand, thus improving running economy.

Gait Retraining

- Gait retraining to reduce lower limb loading rates has shown promise, but has not reduced tibial stress fracture incidence.[18] Studies have shown that subjects can change their running gait to lessen vertical force impact peaks and vertical force loading rates, and that these gait changes can be maintained at 1 month.[23]
- Changes to running biomechanics have been reported in as few as three training sessions.[25,26]
- Crowell et al. demonstrated that gait retraining over eight sessions with real-time visual feedback (accelerometer taped to the anterior medial shin with information displayed on a computer monitor) and verbal cueing resulted in decreased ground reaction forces.[26] Benefits were maintained at 1-month follow up.[26] It is recommended that feedback be progressively decreased for optimal learning and carryover.
- Gait retraining should include verbal and visual cues with an accelerometer, if available, to correct faulty biomechanics identified during the video gait assessment.
  - It is recommended that cues be given in a systematic manner because it is difficult for the athlete to focus on more than one aspect of the running gait and respond to more than one cue.
  - A common biomechanical fault is excessive femoral internal rotation and foot over-pronation. Cues to correct these deviations may include focusing on keeping the knees facing forward and apart, maintaining the arch of the foot, or pushing off the tip of the big toe as opposed to the inside edge of the big toe. Trial and error help determine which cues work best for each athlete.
- Heiderscheitt et al. conducted a laboratory study to determine the effects of cadence manipulation on lower limb joint kinematics and kinetics, concluding that as cadence increases, step length decreases.[27]
  - An increase in cadence by 10% of the runner's preferred cadence leads to decrease center of mass vertical excursion and decreased braking impulse; this is thought to lessen the likelihood of tibial stress fracture.[27]
  - It is recommended that runners manipulate their cadence with the use of a metronome for training. It is possible to download a metronome file as an mp3 and upload it to an mp3 player.

Return to Running

- Address training errors and gradual return to running:
  - Discuss volume of training program and any changes made to the training program in the months before tibial stress fracture. Educate the runner about sensible increases to the training volume and intensity.
  - Treatment and return-to-running decision making is based on the site of the injury and its corresponding potential for healing and risk of significant complication.
  - Most stress fractures heal uneventfully with relative rest and activity modification, however, low-risk does not equate to no risk for those with a stress fracture.
  - A treatment plan should always be tailored to the individual's goals, with discussion of the risks and benefits of continued participation versus absolute or relative rest.
  - Gradual increase in activity should begin after the athlete is pain free and the site is not tender.
- Attempts to quantify graduated training programs through clinical research have not been successful. Despite the lack of research supporting graduated running programs and reduced injury, clinical experience leads one to recommend that a 10% increase per week of training volume OR similar increase in intensity is appropriate to reduce the risk of running-related injury.
  - Several return to running programs have emphasized alternating between days of running and starting at a level between one-third and one-half of the athlete's normal distance and pace.[28-30]
  - It is recommended that the return to run program commence with 5 to 7 minutes of running every second day for the first week and progress weekly provided the athlete is running symptom free.
- Introduction to running following injury is a balance between the dosage and frequency of load applied to the body and the body's ability to adapt.
- It is imperative that biomechanical abnormalities be minimized before the reintroduction of running follow tibial stress fracture.

Periodization

- Undulating

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Training with optimum posture

- Sensorimotor and balance training
- Core training
- Cardiorespiratory training
- Training for optimum muscle balance
- Training for optimum muscle functional strength
- Neuromuscular dynamic stability exercises
- Plyometric training
- Functional training
- Sport-specific training

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of individualization

Application of Acute Training Variables

- Rehabilitation exercises
  - Continue with Phase I exercises, with a focus of high-repetition and low-resistance exercises to build endurance.
- Plyometrics
  - Repetitions:
    - Beginner: 80 to 100 contacts. Intermediate: 100 to 120 contacts. Advanced: 120 to 140 contacts.[31] Aim for eight contacts per set for high intensity exercises. Watch for form failure; if form fails, give the athlete additional rest or reduce the number of repetitions or sets for that day.
  - Sets: two to three per exercise
  - Rest interval: 1:10 to 1:5 work/rest ratio
  - Training frequency: two to three times per week
  - Training volume: higher volume of lower level at the beginning and progress to higher intensity using lower volume.
  - Specific exercises used in the training:
    - Low level
      - Jumping rope
      - Ankle bounces
    - Intermediate level
      - Jumping jacks
      - Barrier jumps (front-back and side-side)
      - Bounding in place
      - Ski jumps
    - High level
      - Tuck jumps
      - Squat jumps
      - Broad jumps
      - Run into bounding
      - Skips for height
      - Double leg → single leg box jumps
      - Scissor kicks
      - Split lunge jumps
      - Power skipping
      - Single leg hops
      - Zig zag hops
      - Depth jumps
- Olympic lifts
  - These exercises are recommended for the elite college runner and not necessarily recreational and age group competitors unless properly coached.
    - Repetitions: three to five
    - Sets: two to three
    - Rest interval: 2 to 5 minutes
    - Intensity: 30% to 40%
    - Repetition tempo: N/A
    - Training frequency: two times per week
    - Training volume: two to four exercises
    - Specific exercises used in the training
      - Snatch
      - Clean and jerk
      - Power clean
      - Hang clean
      - Jump squats
- General weight lifting for strength
  - Repetitions: 10 to 25
  - Sets: two to three
  - Rest interval: 30 seconds
  - Intensity: 20% to 40%
  - Training frequency: two to three times per week
  - Training volume: four to five exercises
  - Specific exercises used in the training:
    - Single leg squats
    - Step ups/downs
    - Calf raises
    - Hamstring curls/straight leg deadlifts
  - Core (include a variety of these exercises; some examples are listed in the following):
    - Front/side planks
    - Back extension
    - Prone alternate arm and leg extension

The preceding recommendations are not considered comprehensive training programs, but rather suggestions to supplement rehabilitation and strength and conditioning programs. Well-rounded programs should consider the following variables: developmental age, training age, gender, and specific mesocycle within the training year.

Sports Performance Testing

General Information

- It is imperative to determine all risk factors associated with tibial stress fracture and develop a systematic rehabilitation approach based on the findings.
- Subjective evaluation should include a thorough history:
  - Previous injury history
  - Volume and intensity of training
  - Type of shoe worn
  - Screen for female athlete triad

Specific Tests

- Closed chain lower limb control during a single leg sit to stand using the following criteria:
  - Balance on one leg and squat back toward an apparatus that is approximately mid-thigh height.
  - *Tap* the apparatus with the buttocks and come back up to starting position in a slow and controlled manner.
  - The athlete needs to be able to avoid the following for 30 consecutive repetitions per limb:
    - Hips Trendelenburg
    - Hip adduction

  - Hip internal rotation
  - Tibial internal rotation
  - Foot pronation
- Video running assessment viewed in slow motion or frame by frame (when high impact activity is appropriate).
  - One minute cadence count while running at a preferred speed (when high impact is appropriate).
    - No biomechanical abnormalities recognized.

Specific Criteria for Progression to the Next Stage to Determine Readiness for Running

- Six to eight weeks is necessary for bone healing.
- High impact activities (plyometrics and running) should be symptom free.

Specific Criteria for Release to Unsupervised Complete Participation in Running

- Pain free running and plyometrics
- No biomechanical abnormalities recognized in follow up video gait assessment viewed frame by frame
- Good lower limb control with all closed chain exercises
- 5/5 Strength of gluteus medius and gluteus maximus
- Solid understanding of gradual changes to running program (distance, speed, topography of training surface)

Recommended Ongoing Exercises

- Hip strengthening and lower limb control exercises listed in Phase I
- Core stabilization exercises
- Cadence work and corrections to biomechanical running style

Evidence

Barrios JA, Crossley KM, Davis IS: Gait retraining to reduce the knee adduction moment through real-time visual feedback of dynamic knee alignment. *J Biomech* 43:2208–2213, 2010.

In this laboratory study, eight healthy, varus-aligned subjects underwent a gait modification protocol. Real-time, visual feedback of dynamic knee alignment was provided with use of a computer monitor over eight training sessions. Over the course of the eight training sessions, feedback was lessened to encourage learning. Natural and modified gait were re-assessed post-training and at 1 month follo up. Comparisons were made within subjects to pretraining gait. The knee adduction moment, as well as hip adduction, hip internal rotation, and knee adduction angles were evaluated. (Level III evidence)

Bennell KL, Malcolm SA, Thomas SA, et al: The incidence and distribution of stress fractures in competitive track and field athletes. A twelve-month prospective study. *Am J Sports Med* 24:211–217, 1996.

Bennell et al. recruited 108 track and field athletes via letters to competitive track and field clubs' coaches and athletes. Subjects were followed for 12 months while they performed their normal training and competition regimen. After 12 months, subjects were questioned by one examiner about injuries sustained and training performed in the 12-month period. The diagnosis of a stress fracture was determined via bone scan or CT scan, using a blinded protocol. Stress fracture per 1000 hours of exposure was calculated for women, men, and all athletes combined. Incidence of stress fracture was also calculated by event. (Level IIb evidence)

Buist I, Bredeweg SW, Lemmink KA, et al: Predictors of running-related injuries in novice runners enrolled in a systematic training program: a prospective cohort study. *Am J Sports Med* 38:273–280, 2010.

The 532 participants from the original GRONORUN study were assessed by a physician and completed a baseline questionnaire before starting the study. Information from these participants was analyzed to determine gender-specific predictors of running-related injury in novice runners training for a 4-mile fun run in this individual cohort study. The authors found different predictors for injuries in male and female novice runners. The authors discussed a couple of limitations of their study. First, the predictors assessed were not inclusive of all potential risk factors to running related injury. Second, exposure to running and running-related injury were self-reported. (Level IIb evidence)

Crowell HP, Davis IS: Gait retraining to reduce lower extremity loading in runners. *Clin Biomech* 26:78–83, 2011.

Crowell et al. hypothesized that peak positive acceleration, vertical force loading rates, and vertical force impact peak would be reduced after a gait training program and that these changes would continue at 1 month follow-up. They performed an a priori power analysis and determined they needed 10 subjects. They chose 10 subjects with high ground reaction forces because high ground reaction forces have been shown to correlate with increased risk of tibial stress fracture. The authors measured tibial acceleration and ground reaction forces of 10 subjects while running overground at a set pace with a standardized running shoe. The subjects underwent a training program that consisted of eight sessions over a 2-week period. At each session real-time visual feedback was used to provide tibial acceleration via accelerometer taped to their anterior shin. Subjects were asked to run softer, make their footfalls quieter, and keep the acceleration peaks below a line placed at 50% of the mean peak positive acceleration. Visual feedback was progressively removed over the last four sessions. Post training data collection was performed immediately following the eighth session and again 1 month later. Significant reductions in the variables were maintained at 1 month follow-up. (Level IIIb evidence)

Distefano LJ, Blackburn JT, Marshall SW, et al: Gluteal muscle activation during common therapeutic exercises. *J Orthop Sports Phys Ther* 39(7):532–540, 2009.

Distefano et al. conducted an experimental laboratory study to determine the electromyographic (EMG) activity of the gluteus maximus and gluteus minimus for 12 commonly used exercises on 21 healthy, physically active subjects who volunteered to participate. Their objective was to quantify and compare EMG amplitude during exercises of varying difficulty to identify which exercises recruit the muscles best. The authors used surface electrodes placed on the gluteus maximus and gluteus minimus. The choice of surface electrodes may be viewed as a flaw because portions of the gluteus medius is deep to the gluteus maximus, gluteal aponeurosis, and iliotibial band. They normalized data collected to a maximal voluntary isometric contraction (MVIC) for hip extension and hip abduction. The method used to measure to

supposedly measure the MVIC of the gluteus medius was to test hip abduction strength in 25° of hip abduction in a side lying position. The standard way to test gluteus medius strength is in an abducted and extended position with slight external rotation. This could skew the results. The exercises tested were well chosen to represent those commonly used in the clinic. They performed a reliability analysis of data collected across the four repetitions of each exercise. $ICC_{3,1}$ values ranged from 0.93 to 0.98 for all exercises except the three versions of a hop. The exercises that produced the greatest gluteus medius EMG signal were side-lying hip abduction (81% MVIC), single limb squat (64% MVIC), and lateral band walk (61% MVIC). For the single limb squat exercise, they encouraged participants to reach for the floor with the contralateral hand to be certain they were squatting deeply enough. However, I believe the form used encourages hip Trendelenburg, which we are trying to avoid. Therefore I do not use this exact style of exercise. The clam exercises with 30° hip flexion and 60° hip flexion scored at the bottom of the list with 40% and 38% MVIC, respectively. However, authors tested this exercise without external resistance. In the clinic it is commonly used with Thera-Band around both legs just above the knees. I believe if the clam exercise were analyzed with resistance, the outcome may be different. Therefore despite the study results, I choose to use this exercise. (Level IIIb evidence)

Heiderscheit BC, Chumanov ES, Michalski MP, et al: Effects of step rate manipulation on joint mechanics during running. *Med Sci Sports Exerc* 43(2):296–302, 2011.

The authors conducted a three-dimensional kinematic and kinetic analysis of the hip, knee, and ankle joints of 45 healthy runners (averaging 29 km/week) volunteering to participate in this experimental laboratory study. Based on a power analysis with minimum power of 80%, 38 subjects were needed to detect a 20% change in joint biomechanics. They recorded data at the subjects preferred step rate, ± 5% and ± 10% of the preferred step rate. Their goal was to characterize lower limb biomechanics at varying step rates, but constant speed during running. The study was well conducted. Further results are discussed in the Final Case. (Level IIIb evidence)

Hreljac A: Impact and overuse injuries in runners. *Med Sci Sports Exerc* 36:845–849, 2004.

Hreljac conducted a review of available evidence to summarize the etiology of running related injuries. (Level V evidence)

Kaeding CC, Yu JR, Wright R, et al: Management and return to play of stress fractures. *Clin J Sport Med* 15(6):442–446, 2005.

Authors performed a Medline search for peer reviewed publications regarding the etiology, classification, treatment, and natural history of stress fractures. They developed an algorithm for treatment of stress fractures based on retrospective case series, evidence-based papers, and the clinical experience of their sports medicine team. (Level IIIa evidence)

Milner CE, Ferber R, Pollard CD, et al: Biomechanical factors associated with tibial stress fracture in the female runner. *Med Sci Sports Exerc* 38:232–328, 2006.

In this retrospective, cross-sectional study, Milner et al. sought to determine the differences in structure and biomechanics between trained female distance runners with a history of tibial stress fracture compared with those without a history of stress fracture. Subjects were recruited by direct contact and fliers posted. Twenty rearfoot strikers with a history of tibial stress fracture were matched for age and mileage to 20 controls without history of stress fracture. A priori power calculations were performed to determine the minimal sample size needed: between 9 and 20 subjects were needed. Subject wore a standard neutral running shoe and ran overground at a standardized speed for 23 meters. (Level IIIb evidence)

Milner CE, Hamill J, Davis IS: Distinct hip and rearfoot kinematics in female runners with a history of tibial stress fracture. *J Orthop Sports Phys Ther* 40(2):59–66, 2010.

In this cross-sectional controlled laboratory study, authors investigated the kinematics of the hip, knee and rearfoot in the frontal and transverse planes of female long distance runners with a history of tibial stress fracture. Subjects ran over ground while data was collected from a force platform. (Level: IIIb evidence)

Niemuth PE, Johnson RJ, Myers MJ, et al: Hip muscle weakness and overuse injuries in recreational runners. *Clin J Sport Med* 15(1):14–21, 2005.

The authors studied hip muscle strength in 30 injured runners compared with 30 uninjured controls in this individual case-control study. Injured subjects were chosen as a convenience sample from an injury clinic. Control subjects were chosen randomly from a pool of volunteers from a distance running club. Injured subjects and controls were matched for gender, weight, and leg dominance. All subjects were considered recreational runners, who were averaging a minimum of 10 miles per week over the last 3 months and not running at a competitive level. Hip muscle strength was recorded using hand-held dynamometry for the hip flexors, extensors abductors, adductors, internal rotators, and external rotators. Measurements were made by a single measurer and normalized to body mass. Results indicated that injured hip abductors and hip flexors were significantly weaker than their uninjured side. The uninjured side's muscles strength was comparable to the controls' muscle strength. The results suggest that unilateral hip muscle weakness exists in injured runners that does not exist in uninjured runners. Given the study design, one cannot conclude a cause-effect relationship. (Level IIIb evidence)

Van Gent RN, Siem D, Van Middelkoop M, et al: Incidence and determinants of lower extremity running injuries in long distance runners: A systematic review. *Br J Sports Med* 41:469–480, 2007.

Van Gent et al. conducted a systematic review with the primary purpose of presenting an overview of the incidence and potential risk factors associated with lower limb injuries in distance runners. They consulted PubMed for published articles up to January 2006. They defined distance runner as an individual running at least 5 kilometers per training or race, but not belonging to an elite group. Authors clearly defined their inclusion and exclusion criteria. They examined 1113 titles and abstracts and narrowed their final selection to 17 articles. The final selection included 13 prospective cohort studies and four retrospective cohort studies. Pooling of the results was not possible. Therefore the authors presented a "synthesis" of the results. Incidence of injury reported varied from 19.4% to 79.3%. Injuries to the hip and pelvis ranged from 3.3% to 11.5%. Females are more likely to be injured. There was conflicting evidence for an association between an increase in training or inexperience in running and running-related injuries. Training volume greater than 64 kilometers per week was a risk factor for running related injury. A history of previous running injury was a significant risk factor for injuries. (Level IIa evidence)

Varner K, Younas S, Lintner D, et al: Chronic anterior midtibial stress fractures in athletes treated with reamed intramedullary nailing. *Am J Sports Med* 33:1071–1076, 2005.

Case series of 7 collegiate-level athletes with 11 chronic anterior midtibial stress fractures followed for a mean duration of 17 months. Each underwent intramedullary nailing. Average return to sport was 4 months. (Level IV evidence)

Zadpoor AA, Nikooyan AA: The relationship between lower-extremity stress fractures and ground reaction force: A systematic review. *Clin Biomech* 26:23–28, 2011.

A systematic review of the literature on the relationship between history of tibial and metatarsal stress fractures and ground reaction forces and loading rate was conducted. A meta-analysis result showed no significant difference in the ground reaction forces between groups. However, the loading rate was significantly different between groups. (Level IIa evidence)

Multiple Choice Questions

QUESTION 1. Research has shown that a manipulation of cadence to what rate has been shown to significantly reduce lower limb forces and risk of stress fracture?

A. Cadence of 180 steps per minute
B. Increase of 15% of runner's preferred cadence
C. Increase of 10% of runner's preferred cadence
D. Cadence of 175 steps per minute

QUESTION 2. High risk stress fractures typically return to sport in:

A. 6 months
B. 4 months
C. 12 weeks
D. 6 to 8 weeks

QUESTION 3. The most common site of stress fracture in a runner is the:

A. Femur
B. Sacrum
C. Fifth metatarsal
D. Tibia

QUESTION 4. Tibia stress fracture is often caused by:

A. Training errors
B. Abnormal biomechanics
C. Strength deficits
D. All of the above

QUESTION 5. True or False

It is thought that poor neuromuscular control and strength of the hip may contribute to running-related injuries.

Answer Key

QUESTION 1. Correct answer: **C** (see Phase II)

QUESTION 2. Correct answer: **B** (see Introduction)

QUESTION 3. Correct answer: **D** (Introduction/ Incidence)

QUESTION 4. Correct answer: **D** (Incidence)

QUESTION 5. Correct answer: **True**

Chapter 37

Tibial Shaft Fractures

INTRODUCTION

Lance E. LeClere, MD, LCDR, MC, USN, and Robert M. Lucas, MD

Epidemiology

- Tibial shaft fractures are the most common long bone fracture treated by orthopedic surgeons.[1]
- Tibial shaft fractures occur at a rate of 26 per 100,000 persons per year.[1]
- The average age of patients that sustain a tibial shaft fracture is approximately 37 years.[2]
- In general, there is a bimodal age distribution for tibial shaft fractures. Most commonly, tibial shaft fractures occur in adolescents and are the result of high energy trauma.[1] A second peak in incidence may occur later in life owing to osteoporosis.[2]
- Tibial shaft fractures are more common in men, at a ratio of approximately 2:1.[3]
- In general, tibial shaft fractures are rarely the result of a sports injury. Most tibial shaft fractures are the result of high-energy mechanisms. High-impact sports and collision sports such as football, rugby, and martial arts are just a few examples. However, some low-energy sports injuries can also cause tibial shaft fractures. This is usually owing to torque and rotational forces on the leg, such as in downhill skiing or gymnastics.
- Tibial shaft fractures can occur via compression, tension, or rotational forces, direct impact, or combination of these forces. In general, tibial shaft fractures sustained during sport are from high-energy, direct impact mechanisms or from low-energy injuries that occur via rotational forces to the leg while the foot is planted on the ground. In the case of downhill skiing, often bindings do not release and a rotational force about the leg results in a spiral tibial fracture (Figure 37-1). Soccer players commonly sustain tibial shaft fractures from direct impact and account for up to 80% of sports-related tibial shaft fractures.[2] These fractures are usually transverse or short oblique in nature (Figure 37-2).

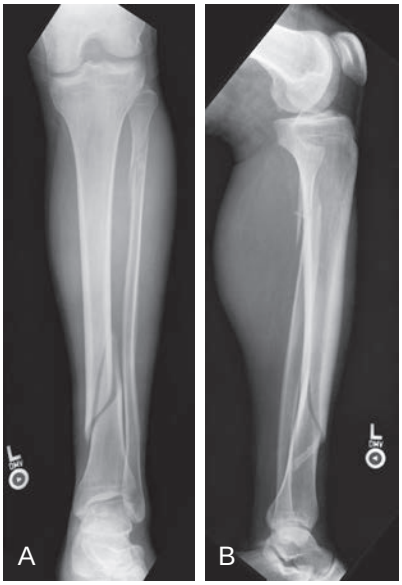

FIGURE 37-1. An anteroposterior (**A**) and lateral (**B**) radiograph of a spiral tibial shaft fracture. These types of fractures are most typically seen as the result of a low-energy, rotational mechanism. One example is a skiing injury.

Pathophysiology

Intrinsic Factors

- There are no specific anatomical, developmental, or neuromuscular factors that specifically predispose an athlete to tibial shaft fractures.
- Metabolic and pathological conditions of the bone such as osteopenia, osteoporosis, infection, and neoplasms may impair bone quality and predispose athletes to tibial shaft fractures.

The views and opinions expressed in this chapter are the those of the authors and are not necessarily representative of the official policy or views of the Department of the Navy, the Department of Defense, nor the U.S. Government.

FIGURE 37-2. An anteroposterior (**A**) and lateral (**B**) radiograph of a transverse tibial shaft fracture. This transverse pattern is often seen in a low-energy direct-impact type of injury, such as in soccer.

Extrinsic Factors

- Extrinsic factors that may predispose athletes to tibial shaft fractures are footwear or equipment that prevents the foot from pivoting or rotating with the leg. For example, skiers who sustained tibial shaft fractures have been found to have binding release values that are higher than noninjured skiers,[4,5] and improvements in the design of ski bindings that allow for release of skis more readily have decreased the incidence of ski-related tibial shaft fractures.[3]
- Failure to wear proper equipment may leave the athlete more prone to fracture from direct impact. Lack of proper protective shin guards in soccer may predispose players to tibial shaft fractures.[6]

Traumatic Factors

- High-energy trauma is the leading cause of tibial shaft fractures. Usually this is a result of direct impact, such as a tackle in football or getting kicked in soccer.
- Fractures that result from low-energy trauma are usually the result of rotational injuries, such as skiing.

Classic Pathological Findings

- Classic findings include pain, soft tissue swelling, gross deformity of the leg on visual inspection, palpable fracture, or even an open fracture.
- Plain radiographs of the tibia and fibula and anteroposterior and lateral planes will confirm diagnosis and allow for fracture classification.

Clinical Presentation

History

- Typically the patient will feel and/or hear a "pop" or "crack" and have the immediate onset of severe pain and inability to bear weight.
- It is important to establish the mechanism of injury because higher-energy injuries may lead to more significant soft tissue damage, swelling, and higher risk of developing compartment syndrome.
- Low-energy injuries or the presence of preceding pain may be related to underlying intrinsic disorders of the bone such as osteoporosis, osteopenia, infection or benign or malignant neoplasms.

Physical Examination

Abnormal Findings

- Tenderness to palpation at fracture site
- Gross deformity on visual inspection
- Significant soft tissue swelling
- Overlying skin or soft tissue damage may be present, such as blistering of the skin or open wounds
- Higher incidence of open fractures caused by limited soft tissue coverage
- Suspicion for possible compartment syndrome should arise when there is pain out of proportion to examination, firm swollen soft tissues, pain with passive stretch of ankle or toes and paresthesias, especially in the deep and superficial peroneal nerve distributions. Pallor, pulselessness, paralysis, and a cool extremity or late signs and concern for significant soft tissue necrosis.

Pertinent Normal Findings

- Nontender along tibial shaft
- No gross deformity of the leg
- No crepitus or motion over the area of maximal tenderness

Imaging

- Anteroposterior and lateral plain radiographs will confirm diagnosis and assist in fracture classification. It is important to include imaging of the knee and ankle.
- The quality of the bone should be taken into account when evaluating plain film x-rays to assess for metabolic, pathological, or infectious conditions and evidence of any previous fractures, which may indicate an underlying disorder.
- Rarely computed tomography (CT) or magnetic resonance imaging (MRI) is required for diagnosis. CT may be helpful in determining whether fracture lines extend into articular surfaces. Heightened concern for intra-articular fractures should arise with spiral fractures in the proximal and distal third of the tibia.[7]
- MRI may be useful in further evaluation in bone and soft tissues if a pathological fracture is suspected.

Differential Diagnosis

- Contusion: No gross deformity will be present. Radiographs will be normal. The patient may or may not be able to bear weight on the affected extremity, although if the patient is able to bear weight the presence of a fracture is significantly less likely.

Treatment

Nonoperative Management

- Cast immobilization (Figure 37-3) with long leg casting or patellar tendon bearing casting.
- Early cast immobilization with transition to Sarmiento functional bracing (Figure 37-4)

Guidelines for Choosing Among Nonoperative Treatments

- Acceptable alignment for nonoperative treatment generally include[1]:
  - Less than 1 cm shortening
  - 5° valgus, 0° varus
  - 10° procurvatum or recurvatum
  - 10° external rotation, 0° internal rotation
- Patellar tendon bearing casts and Sarmiento functional bracing are chosen based primarily on patient and treating physician preference. Large series of functional bracing show excellent healing rates and alignment in properly selected patients.[8]
- Patients who are in poor general health, have significant co-morbidities, or a low preinjury motility status.

FIGURE 37-3. A, An example of a long leg cast used for treatment of a tibial shaft fracture. **B,** An example of a patellar tendon-bearing cast. Often a long leg cast is transitioned to a patellar tendon-bearing cast after initial healing. A patellar tendon cast allows for weight bearing by the patient.

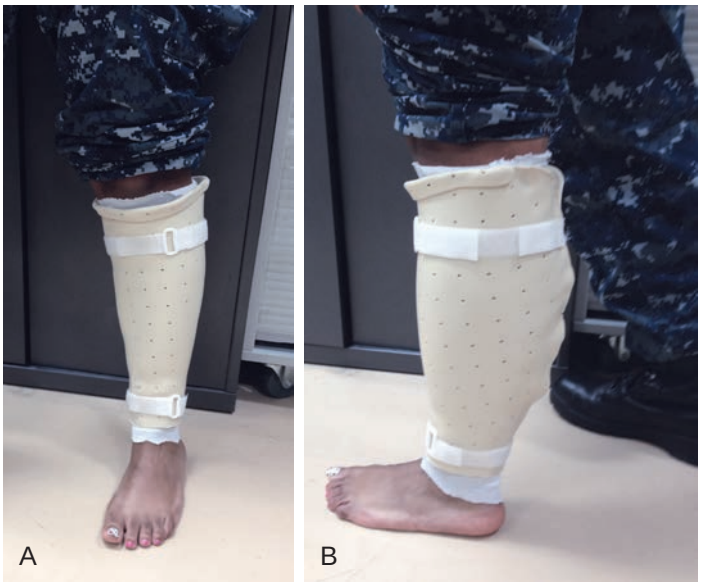

FIGURE 37-4. A,B, A Sarmiento functional brace used for nonoperative treatment of a tibial shaft fracture.

Surgical Indications

- Open fractures (strong relative)
- Neurovascular injury (strong relative)
- Failure to achieve acceptable alignment in cast/brace (relative)
- Patient preference (relative)
- Tibial fracture with intact fibula (relative)
- Extensive bone loss (relative)
- Failure to achieve acceptable closed reduction—see preceding criteria (strong relative)
- Polytrauma (relative)
- Desire for early weight bearing (relative)

Aspects of History, Demographics, or Exam Findings That Affect Choice of Treatment

- Patients who cannot tolerate prolonged cast immobilization or will be poorly compliant with bracing are more suitable candidates for surgical treatment.
- Patients with open fractures or neurovascular damage tend to be treated surgically, although open fracture is not necessarily an absolute indication.
- Surgical treatment has shown lower rates of nonunion, delayed union, and faster time to union.[9,10]
- In general, patients can begin weight bearing earlier with surgical treatment if intramedullary nails are used. Therefore patients who wish to return to full weight bearing or prefer not to be casted are more suitable candidates for surgery.
- Surgeons in North America are more likely to used reamed intramedullary nails for both open and closed tibia shaft fractures.[11]

Aspects of Clinical Decision Making When Surgery Is Indicated

- Most midshaft tibia fractures are treated with intramedullary nailing (Figure 37-5). More proximal or distal fractures or those with severe comminution may be treated with open reduction and internal fixation with plates and screws.[12]
- For intramedullary nailing, a transpatellar or peripatellar tendon approach should be considered. Although the incidence of anterior knee pain is high after intramedullary nailing (67%), there appears to be no advantage of one approach over the other in its prevention.[13]
- Open fractures may be initially treated with external fixation, followed by conversion to intramedullary nailing within 2 weeks; however, they may also be initially treated with either reamed or undreamed intramedullary nailing.[14]
- Patients who develop compartment syndrome require emergent fasciotomies.

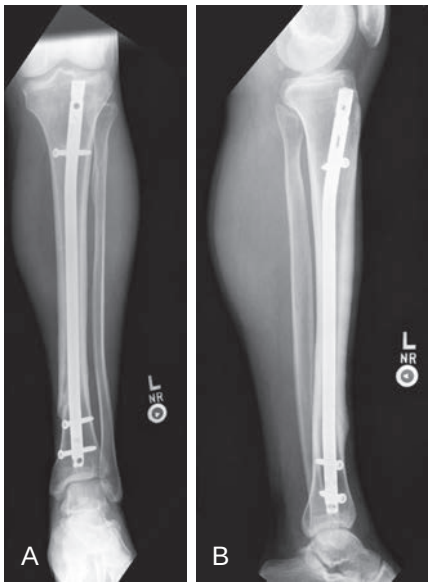

FIGURE 37-5. An anteroposterior (**A**) and lateral (**B**) radiograph of a tibial shaft fracture treated with an intramedullary nail.

Evidence

Bhandari M, Guyatt HG, Swiontkowski MF: Treatment of open fractures of the shaft of the tibia; a systematic review and meta-analysis. *JBJS Br* 83(1):62–68, 2001.

The authors performed a systematic review and meta-analysis of current literature evaluating the effects of various methods of treatment of open tibial shaft fractures. They were able to conclude that unreamed nails reduce the incidence of reoperations, superficial infections, and malunions when compared with external fixators. They were unable to determine whether reamed or unreamed intramedullary nailing was a better treatment option. (Level IV evidence)

Karladani AH, Granhed H, Edshage B: Displaced tibia shaft fractures: A prospective randomized study of closed intramedullary nailing versus cast treatment in 53 patients. *Acta Orthop Sand* 71:160–167, 2000.

The authors randomized patients with closed and grade 1 open tibial shaft fractures to intramedullary nailing versus treatment by closed casting. They found a lower time-to-union, lower delayed union rate, and higher subjective outcome scores with intramedullary nailing. Based off of their results they recommended intramedullary nailing as the preferred treatment. (Level I evidence)

Toivanen JA, Vaisto O, Kannus P, et al: Anterior knee pain after intramedullary nailing of fractures of the tibial shaft. A prospective, randomized study comparing two different nail-insertion techniques. *J Bone Joint Surg Am* 84-A:580–585, 2002.

The authors randomized patients with tibia shaft fractures undergoing intramedullary nailig to treatment with paratendinous or transtendinous nail insertion. They found no significant differences in regard to the rate of anterior knee pain, patient-specific outcome scores, strength, or functional testing between the two groups. (Level I evidence)

Vallier HA, Cureton BA, Patterson BM: Randomized, prospective comparison of plate versus intramedullary nail fixation for distal tibia shaft fractures. *J Orthop Trauma* 25(12):736–741, 2011.

The authors randomized patients with distal tibia shaft fractures to treatment with plate fixation versus intramedullary nailing. They found equal incidience of infection, nonunion, and secondary procedures, with a higher incidence of malalignment in the intramedullary nailing group. (Level I evidence)

Multiple Choice Questions

QUESTION 1. Tibial fractures are most commonly seen in which age group?

A. 5 to 10 years old
B. 14 to 20 years old
C. 30 to 40 years old
D. Over 80 years old

QUESTION 2. The appropriate treatment for tibial shaft fractures is:

A. Casting
B. Bracing
C. Intramedullary nails
D. All of the above

QUESTION 3. Which of the following tibial fracture patterns is most commonly seen in a downhill skier?

A. Transverse
B. Spiral
C. Comminuted
D. Open

Answer Key

QUESTION 1. Correct answer: **B** (see Epidemiology)

QUESTION 2. Correct answer: **D** (see Treatment)

QUESTION 3. Correct answer: **B** (see Epidemiology)

NONOPERATIVE REHABILITATION OF TIBIAL SHAFT FRACTURES

LT Katelyn H. McCormick, DPT, LT, MSC, USN, and Lance E. LeClere, MD

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- Period of non/partial weight bearing for bone callus formation
- Restore full ankle/knee range of motion
- Once full range of motion is established progress to strength training (open kinetic chain)
- Progress weight bearing status, closed kinetic chain strengthening, balance training
- Plyometric training and sport-specific training

Phase I (weeks 1 to 4)

Protection

- If nonsurgical options are selected, the patient will be immobilized with the use of a cast or brace (American Academy of Orthopedic Surgeons guidelines), with possible use of crutches during this time of non–weight-bearing status.

Management of Pain and Swelling

- Nonsteroidal antiinflammatory drugs (NSAIDs)
- Ice
- Compression

Techniques for Progressive Increase in Range of Motion

- Patient will be most likely in a hard cast for approximately 4 to 6 weeks for healing and hard callus bone formation.
- X-rays should be ordered every 1 to 2 weeks for first 4 weeks to ensure there is no displacement of fracture per AAOS guidelines.

Manual Therapy Techniques

- None at this time because the involved area is immobilized and to promote bone healing

Stretching and Flexibility Techniques for the Musculotendinous Unit

- If the patient has a below-knee cast or brace, hamstring stretching is important to facilitate normal gait once cast/brace is discharged/removed.

Other Therapeutic Exercises

- During the acute phase while the patient is immobilized, concentrate on upper extremity and hip strengthening while maintaining non–weight-bearing status, using core strength/stability training.

Activation of Primary Muscles Involved

- Activation of gastrocnemius, soleus, fibularis, and tibialis musculature may be limited due to immobilization during initial phase.
- Depending on the type of casting or bracing, during the initial phase gentle isometrics may be the only way to activate the musculature mentioned in the preceding.

Techniques to Increase Muscle Strength, Power, and Endurance

- While the patient is immobilized in either a cast or brace, lower extremity therapeutic exercises should focus on other lower extremity strengthening to include:
  - Hip abduction
  - Gluteal strengthening
  - Straight leg raises
  - Quadriceps and hamstring strengthening
- The patient will most likely have to perform open kinetic chain exercises at this time secondary to the patient's non–weight-bearing status.

Milestones for Progression to the Next Phase

- Radiographic confirmation of healed fracture site before removal of cast
- Decreased pain

Phase II (weeks 4 to 12)

Clinical Pearl

According to Wolff's law, increased weight-bearing activities can help to determine the formation of bone.[1]

Protection

- If the patient demonstrates an antalgic gait, patient may be issued a CAM walking boot or crutches may be used to decrease forces through the injured area.

Management of Pain and Swelling

- Ice
- Interferential current using electrical stimulation to decrease any pain or swelling following treatment

TIMELINE 37-1: **Nonoperative Rehabilitation of Tibial Fractures**

PHASE I (weeks 1 to 4)	PHASE II (weeks 4 to 12)	PHASE III (weeks 12 to 36)
• Period of immobilization in long- leg cast, patellar tendon bearing cast, or Sarmiento functional bracing • Ice	• AROM/ AAROM/ PROM for full ankle/ knee ROM • Manual talocrural joint mobilizations: Grades I/II → III/IV • Ankle isometrics • Non–weight-bearing ankle strengthening (OKC with Thera-Band resistance) • Stationary bike • OKC strengthening for hip and knee • Lower extremity stretching • Progression of weight bearing status: D/C walking boot/crutches if used • Gait training • Aquatic therapy • Body weight squats, lunges • Leg press/shuttle • Single leg stance/balance activities • Step ups/downs • Elliptical • Initiating walk-jog progression	• Progression of walk-jog progression • Plyometrics • Running/sprints • Agility and sport-specific drills • Return to sport

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Manual techniques will be determined following an assessment of the individual's foot and ankle to include talocrural, subtalar, and first metatarsophalangeal joint mobility.
- Specific techniques will include anteroposterior, posteroanterior, and distraction mobilizations for improving ROM and mobility deficits.
- Mobilizations will start with Grade 1 to 2 and advance to Grades 3 to 4 as the patient tolerates.

Soft Tissue Techniques

- Soft tissue mobilization or massage to the gastrocnemius and soleus complex for increasing flexibility and ankle dorsiflexion range of motion, following a period of immobilization.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Patient should be instructed in how to stretch the gastrocnemius and soleus muscle groups if he or she has limitations in dorsiflexion range of motion.
- Stretching should be continued until normal and symmetrical dorsiflexion ROM is achieved bilaterally. Low-load, long-duration stretching is stretching that takes place multiple times per day (two to three times), for longer hold periods (30 to 60 seconds), and increased repetitions per set (5 to 10 repetitions).
- Active stretching is to be continued once normal ROM is achieved (20- to 30-second hold, two to three sets, one to two times per day).

Other Therapeutic Exercises

- Total lower extremity strengthening should be included as a part of the patient's program to include hip abduction, gluteals, quadriceps, and hamstring musculature.
- Core stability/strengthening exercises such as front and side planks should be incorporated into the strengthening program.
- Total lower extremity strengthening should include lower extremity strengthening to include the hip and thigh musculatures.
- Aquatic therapy/pool based exercise is a beneficial way for progressing weight bearing while performing gross lower extremity ROM and strengthening.
- Initially following removal of cast or brace, instruct the patient in AROM of the ankle to include ankle pumps for improving active dorsiflexion and plantarflexion ROM and pumping out swelling from the distal joints. The patient should also be instructed in ankle circles (clockwise and counterclockwise) for gross ankle range of motion and decreasing swelling of the distal joint segments.
- Ankle isometrics in all directions if initial AROM of the ankle is painful.

Activation of Primary Muscles Involved

- With a tibial shaft fracture and following a period of immobilization, strengthening to all compartments of the distal lower extremity will need to include:
  - Anterior compartment: ankle dorsiflexors (tibialis anterior, extensor digitorum longus, extensor hallucis longus and fibularis tertius)
  - Lateral compartment: ankle everters (fibularis longus, fibularis brevis)
  - Posterior compartment: gastrocnemius and soleus, plantaris, popliteus, flexor hallucis longus, flexor digitorum longus, and tibialis posterior

Open and Closed Kinetic Chain Exercises

- Open kinetic chain exercises: Intrinsic foot muscle strengthening exercises (towel/toe curls exercises and marble pickups) and ankle strengthening exercises (four-way resisted Thera-Band exercises [inversion, eversion, dorsiflexion, and plantarflexion])
- Closed kinetic chain exercises: Progression of weight bearing activities without an increase of pain to include: double leg bridging (Figure 37-6), progressing to single leg bridging; squatting activities with multiple foot positions and bases of support, multi-directional lunges, deadlifts, progression of weight for both double and single leg shuttle/leg press

Sensorimotor Exercises

- Single-leg balance activities progressing from a firm surface to soft/unsteady surface (Figure 37-7)

Functional Exercises

- Beginning of functional exercises as increased weight bearing is tolerated such as squats, lunges (anterior/posterior/lateral), step ups/downs (Figure 37-8)

Milestones for Progression to the Next Phase

- Decreased pain with weight-bearing activities
- Symmetrical lower extremity ROM to include ankle dorsiflexion and knee flexion/extension as measured in open and closed kinetic chain positions

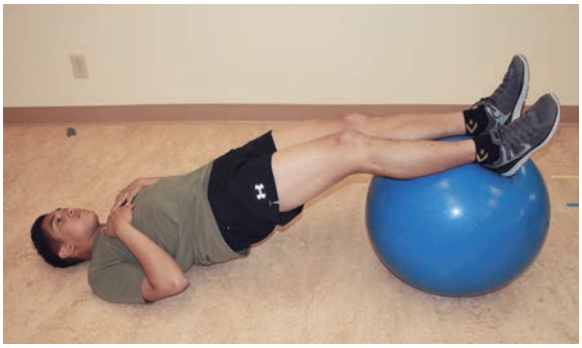

FIGURE 37-6. Double-leg bridging.

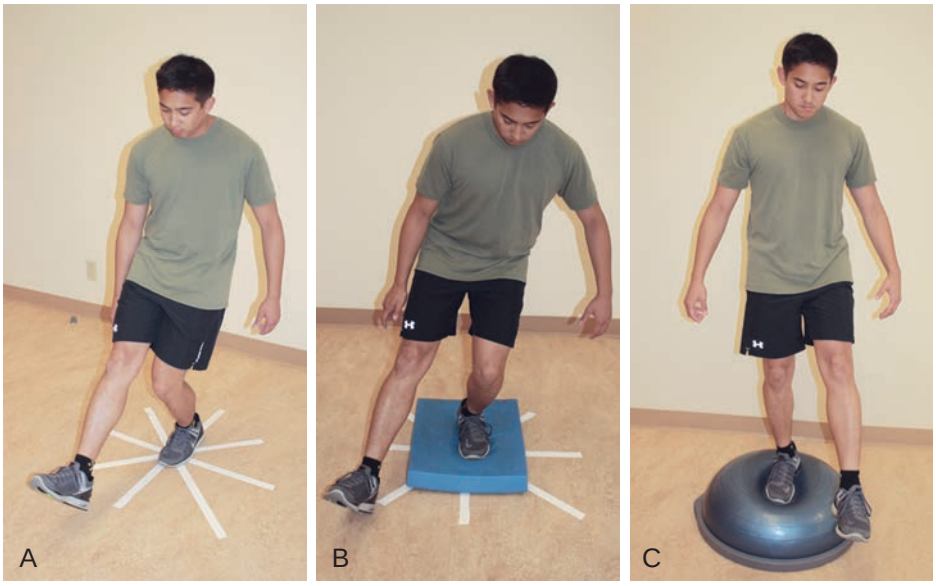

FIGURE 37-7. Single-leg balance activities progressing from a firm surface to soft/unsteady surface. **A,** Ground, steady surface. **B,** Foam, uneven surface. **C,** BOSU balance trainer, uneven surface.

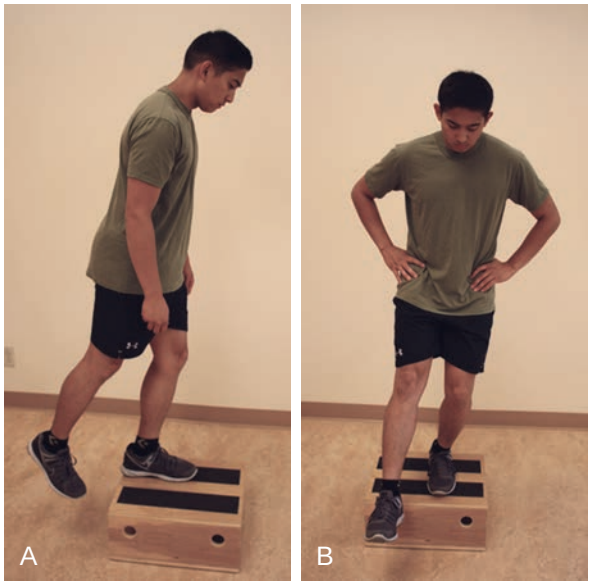

FIGURE 37-8. A, Step up. **B,** Step down.

- Lower extremity strength 5/5
- Normal pain free gait

Phase III (weeks 12 to 36)

Management of Pain and Swelling

- As for Phase II

Techniques for Progressive Increase in Range of Motion

Soft Tissue Techniques

- As for Phase II

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Active stretching to the gastroc/soleus muscle complex along with the hamstring musculature as part of warmup activities before the advancement to higher demand exercises (20- to 30-second hold, two to three repetitions)

Activation of Primary Muscles Involved

- As for Phase III, gross lower extremity and core strengthening for return to athletics is continued

Sensorimotor Exercises

- Progression of single leg balance activities by adding dynamic upper extremity movements or opposite lower extremity movements (Figure 37-9).
- Advance these exercises by increasing the amount of movement, speed of the movement, and the number of repetitions.

Techniques to Increase Muscle Strength, Power, and Endurance

- Progression of closed kinetic chain exercises for dynamic strengthening and endurance for return to sport-related activity

Plyometrics

- Progression to plyometrics begins with partial weight-bearing hops and jumps, starting on Shuttle Systems or in a pool.
- Once partial weight-bearing plyometrics are tolerated, the athlete can progress to full weight bearing activities, including double leg hops moving toward single leg hops and box jumps.

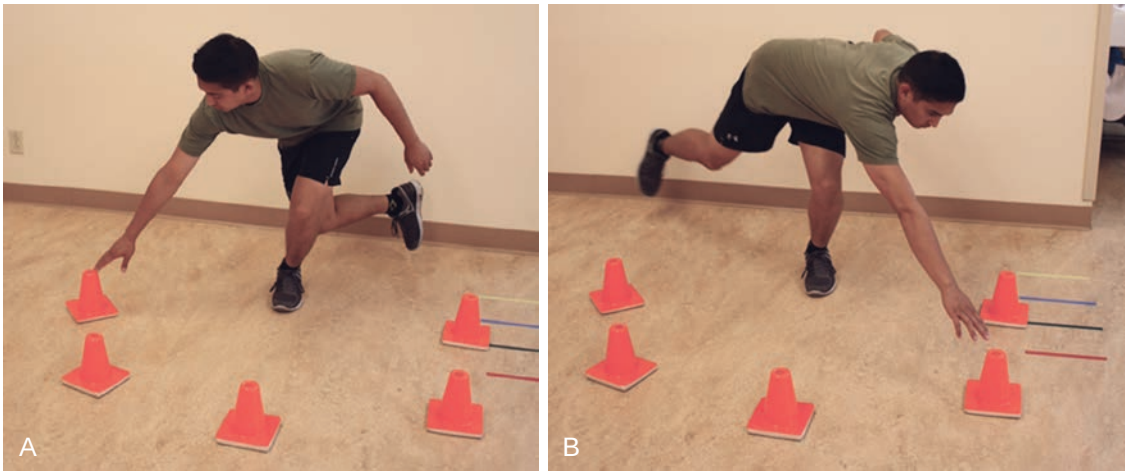

FIGURE 37-9. A,B, Progression of single-leg balance activities by adding dynamic upper extremity movements or opposite lower extremity movements

FIGURE 37-10. Multidirectional movements on unstable surfaces: squats on BOSU balance trainer.

- Box jumps and bounding exercises may be performed to control impact and landing for proper shock absorption and explosive moments.

Sport-Specific/Functional Exercises

- Multidirectional movements to both stable and unstable surfaces such as lunges, squats (on BOSU [Figure 37-10], foam rolls, stability ball)
- Multidirectional plyometric drills to include forward-backward and side-to-side hopping (both with and without outside resistance)
- Walk-jog progression
- Resisted forward and backward running activities

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- Running without symptoms
- Jumping and multidirectional movements without symptoms
- No functional limitations

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention

- Non-healing fracture with increased pain with weight-bearing activities

Performance Enhancement and Beyond Rehabilitation: Training/Trainer and Optimization of Athletic Performance

- Maintaining proper flexibility and strength of the lower extremities for symmetrical gait and performance of functional activities
- Integration of sport-specific training/activities into training program to move from the rehabilitation stage to returning to sport performance level[2]
- Rehabilitation should also include practice/training on multiple surfaces most similar to the athlete's specific practice and competition environment. For example, to return to athletic competition in a sport such as skiing, one should begin with training on flat to moderate terrain and progress to more demanding environments.
- Training should not only focus on strict return to athletic activity, but should also include days of sport-specific drills and rest/work training practice cycles to build up to competition demands.

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Full lower extremity strength and flexibility
- Symptom free during ambulation, running and functional activities

Evidence

Kokmeyer D, Wahoff M, Mymern M: Suggestions from the field for return-to-sport rehabilitation following anterior cruciate ligament reconstruction: Alpine skiing. *J Orthop Sports Phys Ther* 42(4):313–320, 2012.

This article while focusing on rehabilitation after ACL reconstruction, shows how the focus in functional rehabilitation is different when returning an individual to a sport such as skiing, compared with those who play a court or field sport. This article shows that rehabilitation focuses on closed kinetic chain training, eccentric loading, proprioception, and endurance training. (Level V evidence)

Macri F, et al: Validation of a standardized gait score to predict the healing of tibial fractures. *J Bone Joint Surg Br* 94-B:544–548, 2012.

This article showed a correlation of fracture healing when using patient subjective reports of pain with weight-bearing and gait analysis. This information can be beneficial for the understanding of fracture healing and the progression of weight bearing activities during the rehabilitation process. (Level II evidence)

Mueller MJ, Maluf KS: Tissue adaptation to physical stress: a proposed "Physical Stress Theory" to guide physical therapist practice, education, and research. *Phys Ther* 82:383–403, 2002.

This article offers an understanding of the "Physical Stress Theory" and how physical therapists can use this theory for the evaluation, examination, and treatment of patients to positively affect involved tissues and prevent further injuries in the future. The principles in this theory can assist physical therapists in the guided recovering of an individual during the rehab process, while assisting with prevention of future injuries. (Level V evidence)

Turner CH: Three rules for bone adaptation to mechanical stimuli. *Bone* 23(5):399–407, 1998.

This article creates a background of the fundamental principles that help to understand bone adaptation. By understanding how bone develops and adapts to certain stresses and stimuli, this could show possible benefits in early weight-bearing activities for stimulating bone development and healing. (Level IV evidence)

Turner CH, Robling AG: Designing exercise regimens to increase bone strength. *Exerc Sport Sci Rev* 31(1):45–50, 2003.

This article discusses how exercise and an effect on strengthening bones, which can show the benefit of an individual attending rehabilitation services following a fracture. (Level V evidence)

Turner CH, Robling AG: Exercise as an anabolic stimulus for bone. *Curr Pharmaceut Des* 10:2629–2641, 2004.

This article discusses the positive effects that mechanical loading can have on bone tissue and its formation and development. This idea should encourage early-protected weight bearing during the rehabilitation process to help stimulate bone growth and healing. (Level IV evidence)

Turner CH, Robling AG: Exercises for improving bone strength. *Br J Sport Med* 39:188–189, 2005.

This article discusses how certain exercises and weight-bearing activities with proper prescription can have an effect on a bone's density, size, and shape. Based on the theory that weight-bearing exercises can have a positive impact on the growth and development of bone structure, this could show possible benefit in early weight bearing activities following ORIF procedures. (Level V evidence)

Multiple Choice Questions

QUESTION 1. What type of strengthening should first be introduced following the period of immobilization?

A. Isotonic
B. Isometric
C. Isokinetic
D. Plyometric

QUESTION 2. What criteria should be met for the athlete to return to sports?

A. Full Lower extremity range of motion
B. Full strength
C. Normalized gait
D. All of the above

QUESTION 3. What are some of the benefits of performing AROM of the ankle following a period of immobilization?

A. Improving ankle range of motion
B. Strengthening ankle musculature
C. Decreasing swelling
D. A and C
E. All of the above

QUESTION 4. What is one way to determine healing status without the use of an x-ray?

A. Evaluation of one's gait pattern
B. Strength of involved musculature
C. Normal joint range of motion
D. None of the above

QUESTION 5. Ways to challenge one's proprioceptive control during single leg stance activities would include which of the following?

A. Adding uneven/unsteady surfaces
B. Increasing the number of repetitions and sets
C. Increasing amount of movement and speed of opposite upper and lower extremity resisted movements
D. Having the individual close their eyes
E. All of the above

Answer Key

QUESTION 1. Correct answer: **B** (see Phase I)

QUESTION 2. Correct answer: **D** (see Phase III)

QUESTION 3. Correct answer: **D** (see Phase II)

QUESTION 4. Correct answer: **A** (see Phase II)

QUESTION 5. Correct answer: **E** (see Phases II and III)

POSTOPERATIVE REHABILITATION AFTER TIBIAL SHAFT FRACTURE

Katelyn H. McCormick, DPT, LT, MSC, USN, Robert S. Eberly, MD, LCDR, MC, USN, and Lance E. LeClere, MD, LCDR, MC, USN

Indications for Surgical Treatment

- Open fractures
- Neurovascular injury
- Failure to achieve acceptable closed reduction or maintain alignment in cast/brace
- Patient preference
- Tibial fracture with intact fibula
- Extensive bone loss
- Polytrauma
- Desire for early weight bearing

Brief Summary of Surgical Treatment

The goal of surgical treatment is to re-establish acceptable length and alignment in the anteroposterior and lateral planes. Surgical treatment offers the benefit of lower incidence of malalignment, lower nonunion rate, and earlier weight bearing.[1] That being said, surgical management is not free from potential complications. Timing of surgical intervention, a well thought out surgical plan, and respect for the soft tissues all play a role in successful surgical management. It is often said that all fractures are soft tissue injuries with an underlying fracture. Nowhere is this truer than in the leg, where the soft tissue overlying the tibia is minimal and subject to injury from the underlying bony fragments as well as the potential for thermal injury from reaming for intramedullary nailing.

Major Surgical Steps

- Placement of tourniquet as high on the leg as possible and sterile preparation of entire leg with operative leg draped free.
- Place guidewire over the skin and align with the anatomical axis and in-line with the lateral tibial spine. Mark this line to visualize axis throughout case without repeated fluoroscopy images.
- Cut the skin from the inferior pole of the patella to the tibial plateau. Dissect down to patellar tendon and incise and elevate the paratenon off of the tendon medially and laterally to define the borders of the tendon.
- Incise patellar tendon full thickness in-line with the fibers. Bluntly dissect fat pad with your finger down to the tibial plateau.
- Maximally flex the knee and align the guidewire with the anatomical axis. Check your anteroposterior alignment with fluoroscopy. With guidewire in place check your start point on a lateral image of the knee. Ideal start point is parallel with the anterior tibial cortex and on the superior aspect of the flat spot of the articular margin. Angle your hand so that the trajectory of the guidewire will not contact the posterior cortex with a steep angle for an intramedullary trajectory.
- Advance the guidewire 8 to 10 cm into the metaphysis. Confirm position and trajectory on anteroposterior and lateral images. The guidewire should be parallel with the anterior cortex and just medial to the lateral tibial spine. Avoid a posteriorly directed vector.
- Introduce starting reamer with a tissue sleeve to protect the patellar tendon. When reaming your starting hole, if the knee is not hyperflexed your hole will be enlarged anteriorly and will violate the anterior cortical bone. Attention must be paid to keep the knee hyperflexed and to apply a posteriorly directed force to the tissue sleeve.
- Throughout the case reamers will be introduced and removed and it is imperative to retract the skin and not run the reamer in the soft tissue to limit soft tissue injury.
- Bend the guidewire about 15° about 2 cm proximal to the ball tip. If the bend if the guidewire is lined up with

the axis of the t-handle chuck during loading, this can act as a reference for directing the ball tip past the fracture site and directing the wire in the distal tibia. This will allow precise adjustments in trajectory and decrease the number of fluoroscopic images required for determining trajectory.
- Once the starting point has been opened, placement of the knee on a triangle large enough to elevate the foot off the table will extend the knee and assist with reduction.
- Reduce the fracture with manual traction and gross manipulation. Alternately, placement of a universal distractor medially can assist with reduction if there is limited assistance. If using a universal distractor, carefully plan out placement of pins so that they do not interfere with nail placement. Additionally the pins can serve a secondary role as blocking screws if well thought out.
- Additionally pointed reduction forceps, introduced through stab incision at the level of the fracture, can be used for reduction of short oblique fractures.
- Once the reduction is obtained and confirmed with fluoroscopy the guidewire can be passed across the fracture site. Confirm that the wire is intramedullary on anteroposterior and lateral images and advance to the distal tibial physeal scar. The tip of the guidewire should be centrally localized and impacted into subchondral bone to prevent a change in wire trajectory during sequential reaming.
- Measure nail length off of the guidewire. If nail length falls between available sizes use the shorter length to avoid nail prominence.
- Never ream with the fracture unreduced or malreduced. If reamed in a poorly reduced position the nail will only hold the fracture in the nonreduced position in which it was reamed.
- Before reaming estimate the narrowest canal diameter using both anteroposterior and lateral radiographs. Reaming is typically performed 1mm over the diameter of the isthmus to prevent nail incarceration.
- Begin reaming with an end-cutting reamer, usually an 8.5- or 9-mm reamer. Inspect reamer head to make sure threads are clear and sharp. This will reduce the amount of heat generated during reaming. When reaming, the head of the reamer should be past the cortical bone of the proximal tibia before turning on the reamer to avoid distortion of entrance hole.
- All reaming should be on full power, advanced slowly, and pistoned through areas of significant chatter to clear the cutting flutes.
- Care must be taken to not extract the guidewire when the reamer is removed. This is accomplished with back pressure from the wire pusher. Once the reamer has cleared the bone, a hemostat can be used to hold the guidewire in the canal.
- To reduce the thermal damage to bone, reaming should be stopped once reaming is 1 mm greater than the start of endosteal chatter.
- The nail size is selected based on diameter of reaming. Attach the insertion handle to the nail and check that the hole for the proximal interlocking screw is aligned with the handle.
- During insertion of the nail keep the handle aligned with the tibial crest. Keep the knee hyperflexed to prevent iatrogenic fracture of the posterior cortex.
- Once the nail is inserted, confirm depth with lateral fluoroscopy to ensure that nail is not proud in the joint
- In transverse fractures, the distal interlock screw can be inserted first and the nail back-slapped to improve inter-fragmentary compression and gap minimization. Distal interlock screws are placed from medial to lateral using the perfect circles technique. Using fluoroscopy, image the distal hole in the nail and rotate the c-arm and/or patient until the distal holes align and the radiolucent openings form a "perfect circle." Next localize the hole on the skin surface using the tip of a scalpel. When the scalpel tip is in the center of the perfect circle, incise the overlying skin. Bluntly spread down to bone. Next localize the tip of the drill to the center of the distal nail hole while contacting bone. Once the drill tip is in the center of the circle, raise the drill to a position that is collinear with the radiation beam and drill through cortex and nail. Confirm that the drill bit is in the center of the hole and bicortical with orthogonal imaging.
- Measure the depth of your screw with a depth gauge and insert the proper length of screw.
- Proximal interlocking screw can be inserted with the aid of the inserter handle and requires imaging only to confirm the appropriate length of the screw.
- Close peripatellar incision in layers with distinction between patellar tendon and paratenon. Close skin with staples or suture.

Factors That May Affect Rehabilitation

Anesthetic

- If using peripheral nerve block in conjunction with general anesthesia, close attention must be paid to postoperative exams to ensure a compartment syndrome does not go undiagnosed.
- If femoral nerve block is used postoperatively protect patient during weight bearing with a knee immobilizer to prevent falls secondary to quadriceps weakness.

Surgical

- Meticulous surgical dissection with clear delineation of the paratenon from the patellar tendon with separate closures of both layers will help reduce postoperative adhesions.
- Surgical approach (parapatellar vs. tendon splitting) to the starting point does not appear to affect the incidence of anterior knee pain which has been found to be as high as 67% in some studies.[2]

Other Surgical Techniques and Options

- Proximal and distal tibia fractures may be better treated with open reduction and internal fixation with plates and screws.

- Use of proximal dynamic interlock screws to allow for interfragmentary compression with weight-bearing in simple transverse fracture. Do not use in length unstable fractures.

GUIDING PRINCIPLES OF POSTOPERATIVE REHABILITATION

- Early weight bearing as tolerated by patient and dictated by fracture characteristics
- Emphasis on knee range of motion to prevent stiffness and limit scar tissue formation
- Ankle flexion and extension to preserve range of motion and increase venous return

Phase I (days 0 to 14):[1] Immediate Postoperative Period

Clinical Pearl

Early weight bearing as tolerated is recommended following surgical intervention of tibia shaft fractures to assist with bone healing per Wolff's law.[3]

Goals

- Decrease pain and inflammation
- Initiate early range of motion of the ankle and knee
- Initiate early weight bearing

Protection

- Crutches used initially following after surgery, but progressed to weight bearing as tolerated without crutches within 2 to 3 weeks.

Management of Pain and Swelling

- Oral pain medications
- Cryotherapy to reduce pain and inflammation.

[1]Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.

FIGURE 37-11. Mobilization.

- Therapeutic modalities such as TENS and IFC e-stim
- Elevation of surgical limb
- Cryotherapy to reduce swelling

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Grades I, II, and III talocrural, subtalar, distal tibiofibular, mid-foot joint, and patellar mobilizations (Figure 37-11)

Soft Tissue Techniques

- Soft tissue mobilization or massage to the gastroc/soleus complex for increasing flexibility and ankle dorsiflexion range of motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Ankle circles (ABCs), ankle pumps, heel slides, long sitting gastroc/soleus stretching (Figure 37-12) and hamstring stretching

Other Therapeutic Exercises

- Total leg strength: Total lower extremity strengthening should be included as a part of the patient's program to include hip abduction, gluteus, quad and hamstring musculature.
  - Four-way straight leg raises, bridges, hamstring curls, and so on
- Core stability: Front and side planks

TIMELINE 37-2: **Postoperative Rehabilitation After Repair of Tibial Fracture**

PHASE I (postoperative weeks 0 to 2)	PHASE II (postoperative weeks 2 to 8)
• AROM/ AAROM/ PROM for full ankle/knee ROM • Manual talocrural joint mobilizations: Grade I/II → III/IV • Ankle isometrics • Early weight bearing: weight shifting • Gait with crutches: progressing to without • Ice	• AROM/ AAROM/ PROM for full ankle/knee ROM • Manual talocrural joint mobilizations: Grade I/II → III/IV • Ankle isometrics • Non–weight-bearing ankle strengthening (OKC with Thera-Band resistance) • Stationary bike • OKC strengthening for hip and knee • Lower extremity stretching • Gait training • Aquatic therapy (once surgical incision is healed) • Body weight squats, lunges • Leg press/shuttle • Single-leg stance/balance activities • Step ups/downs • Elliptical/StairClimber

FIGURE 37-12. Long-sitting gastroc/soleus stretching. **A,** Non–weight-bearing gastroc stretch (knee extended). **B,** Non–weight-bearing soleus stretch (knee flexed).

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Four-way ankle isometrics: dorsiflexion, plantarflexion, inversion, and eversion

Sensorimotor Exercises

- Front to back and side to side weight shifting to progress tolerance to weight bearing and for proper gait mechanics

Milestones for Progression to the Next Phase

- Able to perform Phase I exercises without pain or increase in swelling
- WBAT (weight bearing as tolerated) without increased swelling to the involved area

Phase II (postoperative weeks 2 to 8)

Goals

- Protection of repaired structures
- Decrease pain and inflammation
- Restore full ROM of the ankle and knee
- Discontinue use of crutches
- Full weight-bearing status
- Restore lower extremity strength

Protection

- Patient to continue use of crutches or straight cane if demonstrates an antalgic gait pattern

Management of Pain and Swelling

- As for Phase I

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Grades I, II, III, and progression to IV as tolerated by patient to the talocrural, subtalar, distal tibiofibular, mid-foot joint, and patellar mobilizations

Soft Tissue Techniques

- Soft tissue mobilization to the gastroc/soleus and hamstring musculature
- Scar mobilizations to surgical incision

TIMELINE 37-2 Postoperative Rehabilitation After Repair of Tibial Fracture (Continued)

PHASE III (postoperative weeks 8 to 16)	Postoperative weeks 16+
• Progression of walk-jog progression • Plyometrics • Running/sprints • Agility and sport-specific drills (week 10)	• Continue with functional lower extremity strengthening and progression to specific sport-related activities • Return to sport

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Patient should be introduced to stretching to the gastrocnemius and soleus muscle groups if patient has limitations in dorsiflexion range of motion. Stretching should be continued until normal and symmetric dorsiflexion ROM is achieved bilaterally. Low load long duration stretching includes stretching that takes place multiple times per day (two to three times), for longer hold periods (30 to 60 seconds), and increased repetitions per set (5 to 10 repetitions). Active Stretching is to be continued once normal ROM is achieved (20- to 30-second hold, two to three sets, one to two times per day).
- Stretching can be progressed from long sitting to standing as tolerated

Other Therapeutic Exercises

- Stationary bike for ankle/knee ROM and low impact cardio
- TLS and core stability strengthening same as Phase I with progression to aquatic-based cardio and strengthening once surgical incisions have healed
- Elliptical and StairClimber for cardio

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Resistance band exercises: DF, PF, INV, and EV (Figure 37-13)
- Four-way ankle isometrics
- Progression of seated heel raises to double leg standing heel raises, then single leg

Open and Closed Kinetic Chain Exercises

- Open kinetic chain exercises: To include: intrinsic foot muscle strengthening exercises: towel/toe curls (Figure 37-14) exercises and marble pickups (Figure 37-15). Four-way resisted Thera-Band exercises (inversion, eversion, dorsiflexion, and plantarflexion).
- Closed kinetic chain exercises: Progression of weight-bearing activities without an increase of pain to include: double leg bridging, progressing to single leg bridging; squatting activities with multiple foot positions and bases of support, multi directional lunges, deadlifts, progression of weight for both double and single leg shuttle/leg press.

Neuromuscular Dynamic Stability Exercises

- Seated BAPS board, progress to standing (Figure 37-16)
- Single leg balance activities progression from a firm surface to soft/uneven surfaces

Functional Exercises

- Beginning of functional exercises as increased weight bearing is tolerated such as squats, lunges (anterior/posterior/lateral), step ups/downs

FIGURE 37-13. Resistance band exercises. **A,** Resisted plantarflexion. **B,** Resisted dorsiflexion. **C,** Resisted inversion. **D,** Resisted eversion.

FIGURE 37-14. A,B, Towel/toe curls.

FIGURE 37-15. Marble pickups.

FIGURE 37-16. Seated BAPS board.

Milestones for Progression to the Next Phase

- Phase II exercises performed without pain or swelling
- Ambulates without assistance device
- Symmetrical lower extremity ROM: to include ankle DF, knee flexion/extension, measured in open and closed kinetic chain
- Lower extremity strength 5/5 (symmetrical bilaterally)
- Normal and pain free gait
- Imaging shows good bone healing

Phase III (postoperative weeks 8 to 16)

Goals

- Continue to improve functional strength
- Progression back to functional activities

Management of Pain and Swelling

- Pain management as for Phase I
- Cryotherapy as needed for swelling

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Grades 2 to 4 to the talocrural, subtalar, distal tibiofibular, mid-foot joint, and patellar mobilizations as needed

Soft Tissue Techniques

- Soft tissue mobilization to the gastroc/soleus and hamstring musculature
- Scar mobilizations to surgical incision as needed

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Patient should be introduced to stretching to the gastrocnemius and soleus muscle groups if patient has limitations in dorsiflexion range of motion. Stretching should be continued until normal and symmetrical dorsiflexion ROM is achieved bilaterally. Low load long duration stretching includes stretching that takes place multiple times per day (two to three times), for longer hold periods (30 to 60 seconds), and increased repetitions per set (5 to 10 repetitions). Active stretching is to be continued once normal ROM is achieved (20 to 30 second hold, two to three sets, one to two times per day).
- Stretching progressed standing as tolerated

Other Therapeutic Exercises

- TLS and core stability strengthening same as Phase II
- Aquatic based therapy: swimming, water jogging
- Elliptical and StairClimber for cardio training

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Resistance band exercises: DF, PF, INV, and EV
- Four-way ankle isometrics
- Progression of seated heel raises to double leg standing heel raises, then single leg (Figure 37-17)

Open and Closed Kinetic Chain Exercises

- Open kinetic chain exercises: To include: intrinsic foot muscle strengthening exercises: towel/toe curls exercises and marble pickups. Four-way resisted Thera-Band exercises (inversion, eversion, dorsiflexion, plantarflexion).
- Closed kinetic chain exercises: Progression of weight-bearing activities without an increase of pain to include: double leg bridging, progressing to single leg bridging; squatting activities with multiple foot positions and bases of support, multi-directional lunges, deadlifts, progression of weight for both double and single leg shuttle/leg press.

Neuromuscular Dynamic Stability Exercises

- Single leg balance activities progression from a firm surface to soft/uneven surfaces, BOSU ball balance, and weight shifting, ball toss with SL balance, star drill
- Resisted side/posterior/anterior stepping (flat foot and on toes)

Plyometrics

- Progression of plyometrics beginning with partial weight-bearing hops and jumping, starting on Shuttle Systems or in a pool. Once partial weight-bearing plyometrics, the athlete can progress to full weight-bearing activities to include double leg hops moving toward single leg hops, and box jumps. Box jumps and bounding exercise may be performed to train for control impact and landing for proper shock absorption and explosive moments.

Sport-Specific and Functional Exercises

- Multidirectional movements to both stable and unstable surfaces: lunges, squats (on BOSU, foam rolls, stability ball)
- Multidirectional plyometric drills to include forward-backward, side-to-side hopping (both with and without outside resistance)
- Ladder drills

FIGURE 37-17. A, Standing double-leg heel raises. **B,** Standing single-leg heel raises.

- Walk-jog progression
- Resisted forward and backward running activities

Milestones for Progression to the Next Phase

- Phase III exercises performed without pain or swelling
- Symmetrical lower extremity ROM: to include ankle, knee flexion/extension, measured in open and closed kinetic chain
- Lower extremity strength 5/5 (symmetrical bilaterally)
- Symmetrical unilateral stance
- Repeat imaging continues to show good bone healing

Outcome Measure

- Foot and ankle disability index (FADI)
- Foot and ankle disability index sport,
- Lower extremity functional scale (LEFS)

Milestones/Criterion-Based Rehabilitation Guidelines for Progression to Discharge

- Performance of Phase III activities without pain or swelling
- Performance of agility and sport specific drills without pain or movement asymmetry
- Hop testing: Involved limb within 85% the distance of the noninvolved limb
- Running gait without asymmetry

Criteria for Return to Sport

- Athletes should be pain free and demonstrate symmetrical ROM and strength
- Symmetry of gait with running, cutting, and pivoting movements
- Symmetry of LE jumping (unloading) and landing (loading)
- Hop tests:
  - Single hop for distance
  - Crossover
  - Triple hop for distance
  - Vertical jump

Evidence

Bone LB, et al: Displaced isolated fractures of the tibial shaft treated with either cast or intramedullary nailing. *JBJS* 79-A(9):1336–1341, 1997.

This article evaluates the functional results of cast treatment in comparison with intramedullary nailing in closed tibial shaft fractures. This study showed that patients managed operatively with nails had better functional outcomes to include preserved alignment and length with a decrease in non-unions. (Level IV evidence)

Kokmeyer D, Wahoff M, Mymern M: Suggesting from the field for return-to-sport rehabilitation following anterior cruciate ligament reconstruction: Alpine skiing. *J Orthop Sports Phys Ther* 42(4):313–320, 2012.

This article, although focusing on rehabilitation following ACL reconstruction, shows how the focus in functional rehabilitation is different when returning an individual to a sport such as skiing, compared with those who play a court or field sport. This article shows that rehabilitation focuses on closed kinetic chain training, eccentric loading, proprioception, and endurance training. (Level V evidence)

Macri F, et al: Validation of a standardized gait score to predict the healing of tibial fractures. *J Bone Joint Surg Br* 94-B:544–548, 2012.

This article shows a correlation of fracture healing when using patient subjective reports of pain with weight-bearing and gait analysis. This information can be beneficial for the understanding of fracture healing and the progression of weight-bearing activities during the rehabilitation process. (Level II evidence)

Mueller MJ, Maluf KS: Tissue adaptation to physical stress: A proposed "Physical Stress Theory" to guide physical therapist practice, education, and research. *Phys Ther* 82:383–403, 2002.

This article offers an understanding of the "Physical Stress Theory" and how physical therapists can use this theory for the evaluation, examination, and treatment of patients to positively affect involved tissues and prevent further injuries in the future. The principles in this theory can assist physical therapists in the guided recovery of an individual during the rehabilitation process, while assisting with prevention of future injuries. (Level V evidence)

Toivanen JA, Vaisto O, Kannus P, et al: Anterior knee pain after intramedullary nailing of fractures of the tibial shaft. A prospective, randomized study comparing two different nail-insertion techniques. *J Bone Joint Surg Am* 84-A:580–585, 2002.

The authors randomized patients with tibia shaft fractures undergoing intramedullary nailing to treatment with paratendinous or transtendinous nail insertion. They found no significant differences in regard to the rate of anterior knee pain, patient-specific outcome scores, strength, or functional testing between the two groups. (Level I evidence)

Turner CH: Three rules for boned adaptation to mechanical stimuli. *Bone* 23(5):399–407, 1998.

This article creates a background of the fundamental principles that help to understand bone adaptation. By understanding how bone develops and adapts to certain stresses and stimuli, this could show possible benefits in early weight-bearing activities for stimulating bone development and healing. (Level IV evidence)

Turner CH, Robling AG: Designing exercise regimens to increase bone strength. *Exerc Sport Sci Rev* 31(1):45–50, 2003.

This article discusses how exercise and an effect on strengthening bones, which can show the benefit of an individual attending rehabilitation services following a fracture. (Level V evidence)

Turner CH, Robling AG: Exercise as an anabolic stimulus for bone. *Curr Pharm Des* 10:2629–2641, 2004.

This article discusses the positive effects that mechanical loading can have on bone tissue and its formation and development. This idea should encourage early-protected weight bearing during the rehabilitation process to help stimulate bone growth and healing. (Level IV evidence)

Turner CH, Robling AG: Exercises for improving bone strength. *Br J Sport Med* 39:188–189, 2005.

This article discusses how certain exercises and weight-bearing activities with proper prescription can have an effect on a bone's density, size, and shape. Based on the theory that weight-bearing exercises can have a positive impact on the growth and development of bone structure, this could show possible benefit in early weight bearing activities following ORIF procedures. (Level V evidence)

Multiple Choice Questions

QUESTION 1. Reaming of the tibia should continue until:

A. First evidence of endosteal chatter
B. 1 mm beyond first evidence of chatter
C. 2 mm beyond first evidence of chatter
D. You can get the largest nail available down the canal

QUESTION 2. Which factors will influence the success of surgical management?

A. Surgical timing with consideration of overlying soft tissue injury
B. Adequacy of reduction before reaming
C. Limiting soft tissue injury at start point
D. All of the above

QUESTION 3. Which of the following is *not* an acceptable technique for reduction?

A. Pointed reduction clamps through stab incisions at fracture site
B. Manual traction and manipulation
C. Reaming through fracture and using the nail to attain reduction
D. Universal distractor with proximal and distal pins

QUESTION 4. Anterior knee pain is associated with which surgical approach?

A. Infrapatellar split
B. Superior transpatellar
C. Lateral peripatellar approach
D. All surgical approaches

QUESTION 5. When is WBAT allowed after surgical intervention?

A. Immediately
B. Week 2
C. Week 4
D. Week 6

QUESTION 6. Which of the following would be used to improve range of motion limitations?

A. Stretching (seated or standing)
B. Joint mobilizations
C. Soft tissue/scar tissue mobilizations
D. All of the above

QUESTION 7. Which of the following is a component of active stretching?

A. Performed until normal and symmetrical DF range of motion is achieved
B. Continued even once normal range of motion is achieved
C. Hold periods are longer (30 to 60 seconds)
D. Increased repetitions per set (5 to 10 repetitions)

QUESTION 8. Which of the following is an example of beginning to initiate plyometrics into an individual's treatment program?

A. Partial weight bearing on shuttle system
B. Partial weight bearing in pool
C. Starting with double leg activities
D. All of the above
E. None of the above

QUESTION 9. When is agility and sport-specific training begun?

A. Week 8
B. Week 10
C. Week 12
D. Week 14

Answer Key

QUESTION 1. Correct answer: **B** (see Surgical Steps)

QUESTION 2. Correct answer: **D** (see Surgical Steps)

QUESTION 3. Correct answer: **C** (see Surgical Steps)

QUESTION 4. Correct answer: **D** (see Surgical Steps)

QUESTION 5. Correct answer: **A** (see Phase I)

QUESTION 6. Correct answer: **D** (see Phase II)

QUESTION 7. Correct answer: **B** (see Phase II)

QUESTION 8. Correct answer: **D** (see Phase III)

QUESTION 9. Correct answer: **B** (see Phase III)

BEYOND BASIC REHABILITATION: RETURN TO SKIING AFTER TREATMENT OF TIBIAL SHAFT FRACTURE

Katelyn McCormick, DPT, LT, MSC, USN

Introduction

ASPECTS OF SKIING THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- Eccentric-loading
- Closed chain
- Acceleration/deceleration movements

- Tibial shaft fractures are a risk with downhill skiing; however, more common injuries include knee sprains and upper extremity injuries.[1]
- Based on past studies, the likelihood of tibial fractures is greater in individuals wearing binding-release valves.[2]
- Factors in tibial fractures include rotational forces, direct collision, and the binding of the ski boot not opening properly.[3]
- For athletes to return to the sport of downhill skiing following a tibial shaft fracture, extensive rehabilitation is recommended to improve full range of motion, flexibility, muscle strength, dynamic stability, and eccentric control.[4]

Literature

- There is limited research discussing the return to skiing following tibial fractures. However, advanced rehabilitation for sport-specific training can begin approximately 8 to 12 weeks post surgery or once the individual is pain free with weight-bearing activities, normal gait, full ankle and knee range of motion, and strength 85% of the opposite lower extremity. Strength testing can be measured through manual muscle testing and/or the use of a hand-held dynamometer.

Phase I: Advanced Strength and Conditioning Programs

Periodization

- Mesocycle: weeks 1 to 4

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Flexibility/joint mobility for joint stability
- Cardiorespiratory training
- Training for optimum muscle functional strength

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload

Application of Acute Training Variables

- During Phase I and early in Phase II of rehabilitation, the main focus is on regaining full range of motion and mobility and strength of the involved joints/segments.
- The acute training variables include choosing certain exercises to progress ROM and strength and determining the order of their effectiveness, the amount of resistance or load, number of repetitions and sets, speed of the exercise and rest breaks.
- There will also be a progression from individual-segment range of motion and strengthening (isometrics, isotonic, concentric and eccentric) exercises to multisegment activities.
- Exercises used in the training include:
  - Four-way hip exercises, straight leg raises beginning weeks 1 to 3 (during initial period of non– or partial weight bearing)
  - Ankle isometrics: seated ankle dorsiflexion and plantarflexion, foot intrinsic strengthening (beginning immediately)
  - Resisted ankle strengthening (beginning weeks 2 to 3)
  - Stationary bike (beginning week 2)
  - Pool therapy:
    - Walking beginning weeks 2 to 3 or once closure and healing of surgical incision is noted
    - Double-leg (DL) heel raises, progressing to single-leg (SL) heel raises starting initially in chest-deep water
    - Pain-free weight shifting/gait training initially with crutches and/or boot approximately weeks 3 to 4
- Specifics:
  - Repetitions: 10 to 15
  - Sets: 2 to 4
  - Intensity: low
  - Training frequency: 2 to 4 days per week, allowing at least 24 hours recovery time between training sessions
  - Training duration: 30 to 60 minutes

Application of Chronic Training Variables

- Chronic training variables include aerobic capacity, anaerobic capacity, flexibility, strength, power, and speed.
- During Phase I in the period of restricted weightbearing, the individual can maintain some cardiovascular

training with the use of the upper body ergometer as early as week 1 and can begin aquatic-based suspended walking and jogging as soon as the surgical incisions are healed.

Phase II: Performance Enhancement Training Techniques

Periodization

- Mesocycle: Weeks 4 to 12

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Flexibility/joint mobility for joint stability
- Sensorimotor and balance training
- Multi-planar training activities
- Training for optimum muscle functional strength and power

Training Principles Used in the Design of the Program

- Progression
- Overload
- Variation
- Principles of specificity

Application of Acute Training Variables

- In Phase II closed chain exercise and functional strengthening are progressed as weight bearing is increasingly tolerated.
- Focus continues to be on achieving full/normalized mobility of involved segments and increasing strength, but also increasing intensity of activities.
- Progression of the number of repetitions and work : rest ratio should also be increased.
- Specific exercises used in training:
  - Continuation of activities from Phase I
  - Aquatic-based therapy for full progression of weight bearing and initial strengthening with less loading
  - Progressive weight-bearing strengthening to begin with double leg/single leg shuttle/leg press
  - Progression of closed chain strengthening to include double leg/single leg heel raises, body weight squats, static and then to multidirectional lunges (Figure 37-18*A*-C). (Progression of these activities can include varying depths of increased knee flexion.)
  - Initiating single leg balance activities: Progression from static to dynamic balance activities (SL on foam surface [Figure 37-19], to ½ foam roll, to more dynamic activities with upper extremity and opposite lower extremity movements).
- Specifics:
  - Repetitions: 8 to 12 repetitions per set
  - Sets: 3 to 5
  - Rest interval: At least 1 minute between sets
  - Intensity: Moderate, working to 85% of full strength by end of phase II
  - Training frequency: Three to four times per week (with at least 24 hours between training sessions)
  - Training duration: 30 to 60 minutes

Application of Chronic Training Variables

- Variables to be considered for chronic training include aerobic and anaerobic capacity/training, strength, speed, flexibility, power, and agility.
- The strength and flexibility of both the involved and uninvolved joint segments should be continually addressed while progressing with speed, power, and agility over time.
- Cardiorespiratory training also needs to continually be addressed, although the individual may not be at his or her normal level of physical training.
- Cardiorespiratory training
  - Aquatic-based exercise to include walking and jogging in variable water depths
  - Stationary cycling: Varying duration and resistance
  - Elliptical trainer
  - Rowing machine
  - Gait training: Using treadmill walking with progression from flat to inclined surfaces

TIMELINE 37-3: **Return to Skiing After Treatment of Tibial Shaft Fracture**

PHASE I (weeks 1 to 3)*	PHASE II (weeks 4 to 8)
• A/AA/PROM of the ankle/knee • Grade 1 and 2 TC joint mobilizations progressing to Grade 3 to 4 • Ankle isometrics • Lower extremity stretching (gastroc/soleus/hamstrings) • OKC hip/knee strengthening • Stationary bike • Progressive ankle resisted strengthening with Thera-Band • Progressive weight bearing • Gait training	• AROM/ AAROM/ PROM for full ankle/knee ROM • Manual talocrural joint mobilizations: Grade I/II → III/IV • Ankle isometrics • Non–weight-bearing ankle strengthening (OKC with Thera-Band resistance) • Stationary bike • OKC strengthening for hip and knee • Lower extremity stretching • Gait training • Aquatic therapy (once surgical incision is healed if treated operatively) • Body weight strengthening: squats, lunges • Leg press/shuttle • Single leg stance/balance activities • Step ups/downs • Elliptical/StairClimber

*Mild variation in treatment timeline depending on surgical fixation versus nonoperatively managed.

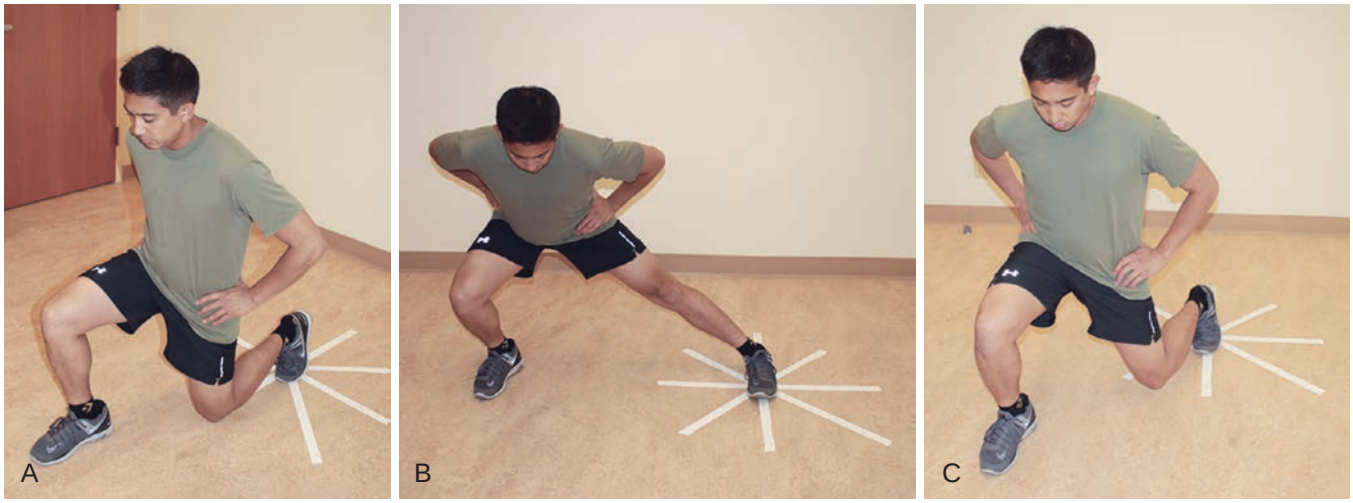

FIGURE 37-18. Multidirectional lunges. **A,** Anterior lunge. **B,** Lateral lunge. **C,** Diagonal lunge.

FIGURE 37-19. Single-leg balancing on a foam surface.

Phase III: Sport-Specific Training

Periodization

- Mesocycles: Weeks 12 to 36

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Multiplanar training activities
- Training for increasing functional strength and power
- Neuromuscular dynamic stability exercises
- Plyometric training
- Functional training

TIMELINE 37.3 **Return to Skiing After Treatment of Tibial Shaft Fracture** (Continued)

PHASE III (weeks 8 to 12)	PHASE IV (weeks 12 to 36)
• Continued closed kinetic chain lower extremity strengthening and single leg proprioceptive training • Progression of walk-jog program • Plyometrics: starting with partial weight bearing such as in pool or on shuttle system and progressing to full weight bearing • Functional testing	• Multi-planar training activities • Progression of plyometric training • Neuromuscular dynamic stability exercises • Eccentric CKC training • Sport-specific drills • Outcome testing and assessment

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload
- Principle of variation
- Principle of individualization
- Principle of specificity: Specific adaptation to imposed demands (SAID)

Application of Acute Training Variables

- During this phase of rehabilitation, much of the focus is on dynamic functional activities that are symmetrical bilaterally.
- There should be an increase in the number of repetitions, sets, speed, range of movement, different types of contraction, and decreasing rest periods.
- There will also be a progression of plyometric activities. Progression of plyometrics include type of activity, intensity, and specifics to sport-related training (such as eccentric phase of plyometric exercises).[4] Plyometric activities should not exceed three times per week, allowing for approximately 48 hours rest between training sessions.
- Specifics:
  - Repetitions: Plyometrics 30 to 140 contacts per session
  - Sets: 3 to 5
  - Rest interval: work-to-rest ratio of 1:5 to 1:10 for plyometrics
  - Intensity: Moderate to high
  - Training frequency: One to three times per week (no consecutive days)
  - Training duration: 30 to 90 minutes
  - Strengthening: Front squats, lunges, step ups, jump squats, eccentric training
- Neuromuscular stabilization and plyometrics: focus on single and double leg eccentric loading: DL/SL squat holds, then progressing to uneven surfaces such as half foam rolls/BOSU (Figure 37-20*A,B*) and adding sport cord resistance and outside source perturbations
  - Phase I Plyometrics: Two-foot ankle hops, double-leg squat jumps, double-leg jumps over obstacle (forward and lateral)
  - Phase II Plyometrics: Single-leg hops (vertical, forward and backward, side to side)
  - Phase III Plyometrics: Box or BOSU jumps (Figure 37-21*A*-*C*) (double- and single-leg): jump up, progress to jump down, forward/lateral jumps, increasing heights
- Specific exercises used in training:[5]
  - Progression of skiing initially on flat groomed surfaces, progressing to more challenging terrain

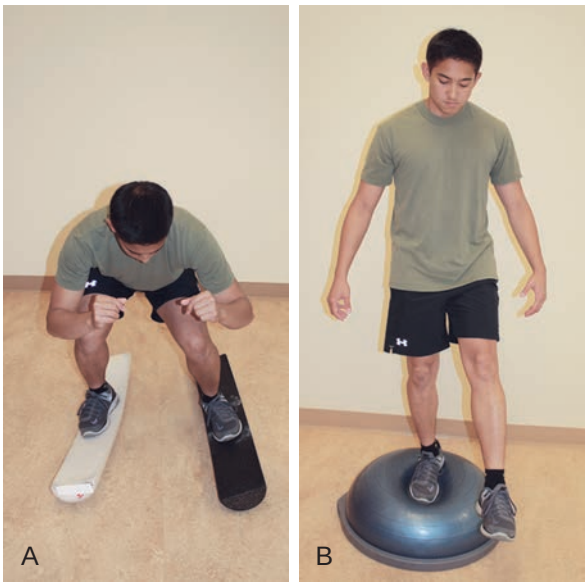

FIGURE 37-20. Single- and double-leg eccentric loading on uneven surfaces such as (**A**) half foam rolls and (**B**) BOSU ball.

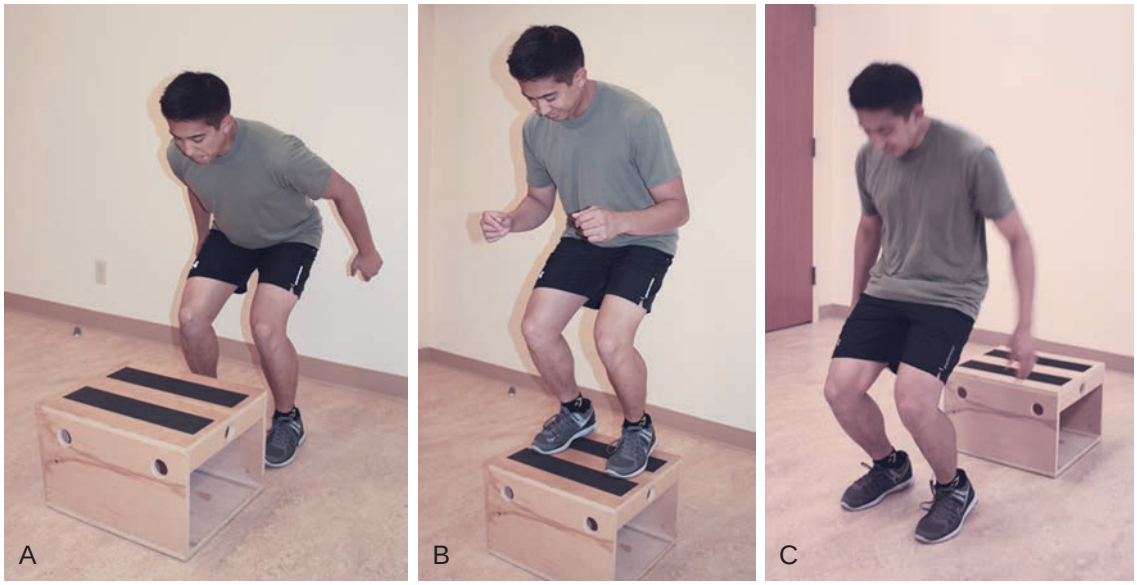

FIGURE 37-21. A-C, Box jumps (double and single leg). Jump up, progress to jump down, forward/lateral jumps, increasing heights.

- Side slipping: smooth and distinctive stops
- Progression of turns: neutral stance, squat position, single leg, turns with hops

Application of Chronic Training Variables

- Chronic training variables are focused throughout the final training phase by making sure there is a normalization of strength, endurance, speed flexibility, power, and agility when comparing the involved with the uninvolved side.
- The focus is on making sure movement patterns are being performed in correct form, without compensatory mechanisms, which could lead to other injuries and lack of full recovery.
- Specific training focused on an individual component should be performed on alternating days, but training sessions should include periods of utilizing multiple chronic training variables for full return to specific sport.

Sports Performance Testing

General Information

- General history: Training background, future occupational and sport demands/goals
- Medical history: General health, other health conditions, medications, systemic diseases, previous injuries (sport or non–sport related)
- Surgical History: Lower extremities, spine, and so on.
- Outcome surveys: Lower Extremity Functional Scale, Foot and Ankle Outcome Scale and Foot and Ankle Ability Measure (FAAM; depending on location of tibia fracture)
- Sports injury history: Current injury history to include other injuries to the lower extremity or spine, mechanism of injury, when it occurred

Specific Criteria for Progression to the Next Stage to Determine Readiness for Skiing

- Progression from one phase to the next is determined by one's performance, including adequate range of motion, strength, and functional activity assessment such as gait mechanics, not on time alone.
  - Functional testing can be assessed by evaluating activities such as double/single squatting, hop testing, and gait and running mechanics.
- For example, progression to Phase II begins when the individual is full weight bearing and full range of motion of the ankle.
- Progression to Phase III occurs with no pain with weight-bearing activities, full ankle ROM in both closed and open kinetic chain positions, full and symmetrical strength, and normal and pain-free gait.
- Objective tests
  - Dynamic muscle performance testing
    - Double and single leg squat holds assessing the hold time for endurance while maintaining proper knee varus and valgus alignment starting at 2 to 3 months.
  - Movement performance testing:
    - Ankle ROM to include closed kinetic chain assessment of DF beginning at 2 to 3 months
    - Functional movement screening: First assessment at approximately 2 to 3 months. Waiting to perform this screen allows time for regaining full ankle range of motion and restoring lower extremity strength, to limit the number of factors that would be contributing to the deficits in their results.
  - Sport-specific testing (balance and stabilization testing) starting at 3 months. The individual should have full range of motion and 5/5 strength, along with a minimum of 85% side to side symmetry for returning to full participation in sports.
    - Static stand
    - Single leg squat
    - Single leg hop for distance
    - Single leg hop down from 12-inch step
    - 6-meter timed hop for distance
    - Triple hop for distance
  - The difference between an athlete returning to skiing rather than a sport such as basketball is the need for closed kinetic chain control.
- Other tests
  - Isokinetic testing of ankle DF/PF and INV/EV if available
    - Involved limb should show a minimum of 85% side to side symmetry when compared with the uninvolved limb.

Specific Criteria for Release to Unsupervised Complete Participation in Skiing

- Before being released to participation in their specific sport, the individual should have normal and pain-free walking and running gait.
- The individual should also have at least 85% strength, which can be measured by manual muscle testing and/or use of a hand held dynamometer and functional assessment of the involved lower extremity compared with the noninvolved side. Strength testing would be an example of quantitative measure, along with results from functional testing such as distance achieved on single leg hop tests. However, the quality of the movement will also need to be evaluated and determined for the individual to return to his or her desired sport. The individual's movement pattern, point of fatigue, and substitutions are all qualitative ways at evaluating his or her movement pattern.
- The individual should show a minimum of 85% side to side symmetry on all testing before full return to sports.

Recommended Ongoing Exercises

- Even after the athlete has returned to the sport of skiing, neuromuscular stabilization training should continue, focusing on eccentric control with closed kinetic chain activities, multi-planar dynamic squats and lunges, along with sport specific training and drills.

Evidence

Berg HE, Eiken O: Muscle control in elite alpine skiing. *Med Sci Sports Exerc* 31:1065–1067, 1999.

This article was used to gain an understanding of the muscle control needed with different skiing events. Using this information allows for an understanding of the different stresses and activities an individual would need to perform to return to a specific skiing activity and assist with guiding the rehabilitation process. (Level IV evidence)

Burkner A, Simmen HP: Fractures of the lower extremity in skiing: The influence of ski boots and injury pattern. *Sportverletz Sportschaden* 22(4):207–212, 2008.

This article looked at what were some of the major causes of tibial fractures when participating in downhill skiing activities. (Level IV evidence)

Deibert MC, Aronsson DD, Johnson RJ, et al: Skiing injuries in children, adolescents and adults. *J Bone Joint Surg Am* 80:25–32, 1998.

This was a prospective study that was performed to gather information on skiing injuries, to include the age group that had the most injuries, the most common injuries, and what some of the causes of injury. (Level IV evidence)

Koehle MS, Lloyd-Smith R, Taunton JE: Alpine ski injuries and their prevention. *Sports Med* 32:785–793, 2002.

This article looks at some of the possible causes of lower limb injuries during skiing. By having a better understanding of how individuals get injured, it could allow for future prevention. (Level V evidence)

Kokmeyer D, Wahoff M, Mymern M: Suggestions from the field for return-to-sport rehabilitation following anterior cruciate ligament reconstruction: alpine skiing. *J Orthop Sports Phys Ther* 42:313–325, 2012.

This article while focusing on rehabilitation following ACL reconstruction, shows how the focus in functional rehabilitation is different when returning an individual to a sport such as skiing, compared with those who play a court or field sport. This article shows that rehabilitation focuses on closed kinetic chain training, eccentric loading, proprioception, and endurance training. (Level V evidence)

Multiple Choice Questions

QUESTION 1. Which of the following is not required to begin advanced rehabilitation for sport-specific training?

A. Full AROM
B. Full strength
C. Pain-free weight-bearing activities
D. Normal gait mechanics

QUESTION 2. Which of the following is not a common cause of tibial fractures while skiing?

A. Rotational forces
B. Direct collisions
C. Traction of the joint
D. Type of binding of the ski boots

QUESTION 3. What is the benefit of an aquatic-based program in the initial phases of rehabilitation?

A. Initiate early protected weight bearing
B. Continue cardiovascular conditioning
C. Gait training
D. All of the above

QUESTION 4. During sport-specific training, what factors are important to consider during the progression of plyometrics?

A. Specific sport
B. Type of activity
C. Intensity
D. Rest periods
E. All of the above

QUESTION 5. Which sport-specific functional testing would be the most beneficial for a skier to return to sport?

A. Single leg squat
B. Single leg hop for distance
C. Triple hop for distance
D. 6-meter hop for distance

Answer Key

QUESTION 1. Correct answer: **B** (see Introduction)

QUESTION 2. Correct answer: **C** (see Introduction)

QUESTION 3. Correct answer: **D** (see Phase 1)

QUESTION 4. Correct answer: **E** (see Sport-Specific Training)

QUESTION 5. Correct answer: **A** (see Specific Criteria for Progression to the Next Stage to Determine Readiness for Skiing)

Chapter 38

Achilles Tendinopathy and Rupture

INTRODUCTION

James H. Flint, MD, LCDR, MC USN Michael D. Rosenthal, PT, DSc, SCS, ECS, ATC, CSCS, and John-Paul H. Rue, MD, CDR, MC USN

Epidemiology

- Rising incidence of Achilles tendinopathy and rupture caused by increasing participation in recreational and competitive sports
- Most commonly an overuse injury from repetitive strain, as opposed to traumatic etiology
- Age: typically middle age (mean 40 years old)
- Sex: Men greater than women (although incidence in women increasing as participation in sports increases)
- Sport: mid- to long-distance running and jumping sports; basketball very common for acute rupture in recreational athletes
- Sports position: None specific; any position that involves repetitive excess load on the Achilles tendon

Pathophysiology

Intrinsic Factors

- Advancing age
- Gender
- Abnormal dorsiflexion range of motion
- Abnormal subtalar range of motion
- Decreased plantar flexion strength
- Forefoot varus
- Cavus foot
- Improper conditioning/training
- History of intratendinous or peritendinous corticosteroid injection
- Recent history of fluoroquinolone use
- Genetic predisposition possible
- Co-morbidity: obesity, hypertension, diabetes, high cholesterol

Extrinsic Factors

- Repetitive forceful loading or sudden extreme loading of the Achilles tendon (e.g., strong eccentric loading as when landing from a jump shot)
- Training errors[1]
  - Excessive mileage (volume)
  - Increase in training intensity
  - Uneven training surfaces (i.e., hills, excessively crowned roads)
- Environmental factors
  - Slippery and/or uneven roads/courts
- Inadequate equipment
  - Improper footwear (nonathletic shoes, unevenly worn/warped shoes)
- Previous injury

Traumatic Factors

- Direct trauma or penetrating injury to the Achilles tendon
- Repetitive microtrauma within the tendon from excessive or frequent activity with inadequate rest periods

Classic Pathological Findings

- Paratenonitis: thickened paratenon, adherent to underlying tendon. Inflammatory infiltration of the paratenon seen microscopically.
- Paratenonitis with tendinosis: combination of paratenonitis and tendinosis

The opinions herein are those of the authors and not the official policy or position of the United States Government, Department of Defense, or Department of the Navy.

- Tendinosis: Noninflammatory degeneration of tendon fibers. Tendon may appear discolored and thickened or nodular. Microscopically: lack of inflammatory cells, scattered neovascularization, possible necrosis and/or calcification. Typically appears 2 to 6 cm proximal to the calcaneal insertion.
- Rupture (partial or complete): frank disruption and separation of tendon fibers. Evidence of tendinosis typically present.

Clinical Pearl

The majority of Achilles tendon problems are in the category of tendinosis.[2] In addition to a lack of inflammatory cells, ultrastructural findings include altered cellular (collagen) alignment and increased vascularity. This altered tendon structure has been shown to improve with eccentric loading.

Clinical Presentation

History

- Middle-aged recreational athlete or "weekend warrior"
- For elite athletes, inquire about changes/increases in training intensity and/or duration
- For paratenonitis: focal pain and tenderness after activity; progresses to symptoms at beginning of activity or with less intense/routine activities
- For tendinosis: typically nonpainful, patient may complain of swelling or nodularity of the tendon
- For acute rupture (partial or complete): patient may describe feeling of being kicked in the back of the leg, a severe cramping sensation, or feeling a "pop"
- Inquire about previous history of treatment, to include corticosteroid injection(s) or recent use of fluoroquinolone antibiotics.

Physical Examination

- Warmth, thickening, swelling, and/or crepitus
- Tenderness to palpation, typically 2 to 6 cm above the calcaneal insertion
- Tendon nodularity (painful when paratenonitis present, painless if pure tendinosis)
- Positive "painful arc sign": pain originating within the tendon will move with ankle movement, whereas pain caused by paratenonitis will remain fixed
- Calf atrophy
- Decreased/painful ankle dorsiflexion
- Specific to partial or complete rupture
- Palpable defect in the tendon (Figure 38-1)
- Hematoma/ecchymosis
- Inability to perform single heel rise or decreased plantar flexion strength
- Positive Thompson test: lack of foot plantar flexion with compression of superficial calf (Figure 38-2)

Clinical Pearl

When performing the Thompson test, position the patient in the prone position. The knee may be flexed or extended (have the foot hang off the end of the exam table). Ensure that you isolate the superficial posterior compartment of the calf (gastro-soleus complex). Compressing the entire calf will stretch the deep posterior compartment (FHL, FDL, tibialis posterior), which can result in false plantar-flexion of the foot. Comparison with the contralateral side is recommended to assess for asymmetry of the magnitude of plantarflexion.

FIGURE 38-1. A palpable gap is characteristic of a complete tendon rupture.

- O'Brien needle test: a sterile needle placed perpendicularly in the tendon, proximal to the injury, will move in the opposite direction of foot plantarflexion or dorsiflexion if the tendon is intact distally
- Hyper-dorsiflexion sign: with the patient prone and knees bent 90°, maximal passive dorsiflexion of the feet will show asymmetry. Increased dorsiflexion (DF) on the injured side indicates a loss of DF restraint provided by the Achilles tendon.

FIGURE 38-2. The Thompson test. Intraoperative exam bilaterally showing no plantarflexion of the right foot when the superficial compartment is compressed.

FIGURE 38-3. Plain radiograph in a patient with posterior ankle pain. Note the presence of an os trigonum.

Imaging

- Plain radiography: not particularly helpful for Achilles tendinopathy, but may help rule out other diagnoses (i.e., symptomatic Os trigonum, Haglund deformity). Soft tissue swelling typically present with partial or complete rupture (Figure 38-3).
- Ultrasound: fast and inexpensive. May reveal peritendinous fluid or adhesions (as with tendinopathy), or partial/complete rupture on dynamic exam. Color Doppler may show abnormally increased blood flow. Potential utilization of US in determination of operative or conservative management of Achilles ruptures.[3]
- Magnetic resonance imaging (MRI): usually second-line after ultrasound because of cost. Extremely helpful in classifying tendinopathy and for diagnosing partial and complete tendon tears (Figures 38-4 and 38-5).

Differential Diagnosis

- Acute rupture
- Partial rupture
- Achilles tendinopathy
- Retrocalcaneal bursitis—often associated with Haglund deformity. Pain localized to insertion site of Achilles tendon, however, will be anterior to the actual tendon on exam.
- Insertional tendinosis—often associated with Haglund deformity. History may include aggressive hill running. Pain is localized to Achilles tendon insertion.
- Symptomatic Os trigonum—pain with foot plantar flexion, as when going downstairs. Plain x-ray will reveal the symptomatic ossicle.
- Posterior ankle impingement
- Posteromedial tendon tendinopathy (tibialis posterior, flexor hallucis longus)[2]
- Subluxation/dislocating peroneal tendons—pain/discomfort at distal aspect of lateral malleolus, typically with feeling of popping or clicking. If severe enough, will be reproducible on physical exam. MRI helpful in making definitive diagnosis when exam is equivocal.
- Sever's disease
- Sural neuritis
- Systemic disease

Treatment

Nonoperative Management

Nonsurgical treatment options for Achilles tendinopathy include[1]:

- Ankle/foot orthosis (AFO) to correct mechanical misalignment(s)
- Nonsteroidal antiinflammatory drugs (NSAIDs)
- Modification of training programs or sports activities (relative rest)
- Physical therapy

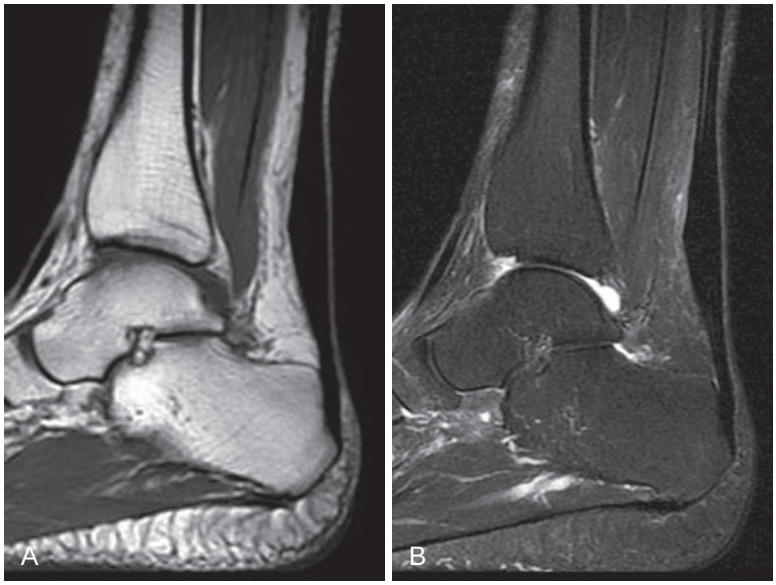

FIGURE 38-4. Typical T1-weighted (**A**) and T2-weighted (**B**) MRI findings in a patient with Achilles tendinosis. Note the thickened tendon without significant inflammatory findings on T_2-weighted images.

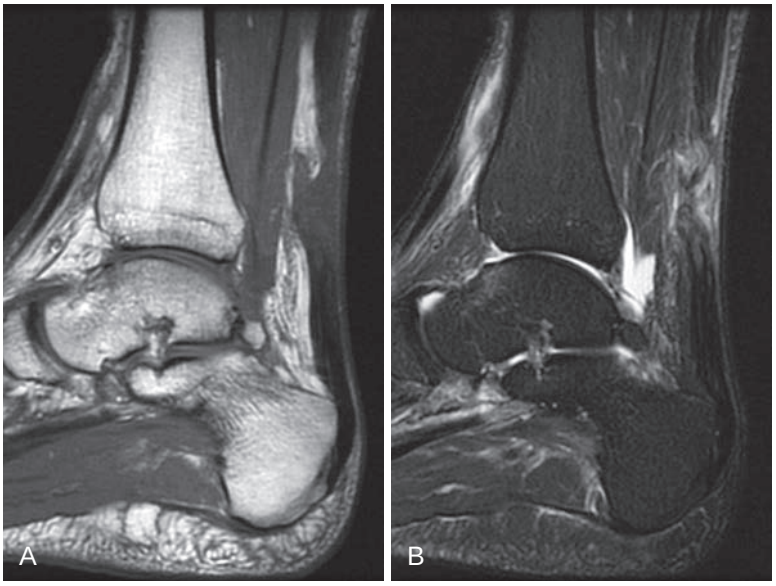

FIGURE 38-5. MRI of a patient with an Achilles tendon rupture. T1-weighted (**A**) and T2-weighted (**B**) images show frank disruption of the tendon fibers.

- Eccentric training exercises
- Brisement (injection of anesthetic or saline into paratenon sheath to break adhesions; for paratenonitis only)
- Extracorporeal shock wave therapy
- Corticosteroid injection—generally contraindicated because of risk of tendon disruption; however peritendinous injection has been beneficial in some cases of paratenonitis.
- Sclerosing agent injections (i.e., Polidocanol)
- Prolotherapy
- Air Heel brace[4]
- Night splints
- Low-level laser therapy
- Iontophoresis
- Stretching exercises
- Soft tissue and joint mobilizations (manual therapy)
- Taping
- Heel lifts
- Night splints

Nonsurgical treatment options for Achilles rupture include:

- Casting/bracing
- Accelerated functional rehabilitation[5]

Guidelines for Choosing Among Nonoperative Treatments

- For older individuals who are less athletic/active, treatment will initially consist of immobilization (along with rest and ice) of the lower leg with subsequent integration of conservative rehabilitation methods to restore mobility, strength, and functional capability.
- For younger, more active patients, or athletes, relative rest with modification of training regimens is important. The same conservative measures also apply.
- For tendinopathy, eccentric training exercises have been shown to be beneficial[4,6–10]
- If initial conservative measures fail, additional nonsurgical treatment options may be pursued depending on patient desire and willingness

Surgical Indications

Surgical treatment options for Achilles tendinopathy include:

- Percutaneous tenotomy
- Open paratenon and/or tendon debridement/excision (with tendon repair/reconstruction as indicated)

Surgical treatment options for Achilles rupture include:

- Open repair
- Percutaneous repair
- Open repair with lengthening, augmentation, or reconstruction (for chronic ruptures)

Surgical indications for Achilles tendinopathy:

- Absolute indications: none
- Relative indications: Achilles tendinosis (or paratenonitis with tendinosis) that is resistant to conservative measures

Surgical indications for Achilles rupture (acute or chronic):

- Absolute indications: open wound requiring irrigation/debridement
- Relative indications: failure of nonoperative measures, elite athletes who desire faster return to activity
- Choice of operative treatment should ultimately fall on the patient after appropriate discussion of the risks, benefits, and alternatives to surgery.

Aspects of History, Demographics, or Exam Findings That Affect Choice of Treatment

- Age
- Participation in competitive sports
- Severity/persistence of symptoms
- Adherence to prior interventions
- Response to prior treatments

Aspects of Clinical Decision Making When Surgery Is Indicated

- Patient characteristics (i.e., age, athlete or nonathlete)
- Underlying medical conditions (i.e., diabetes, peripheral vascular disease, skin condition)
- Patient preference

- Among athletes, desire to begin earlier, more aggressive rehabilitation with possible earlier return to activity
- Occupational/sports demands

Multiple Choice Questions

QUESTION 1. Extrinsic factors associated with Achilles tendinopathy and ruptures include all of the following except

A. change in intensity of training program.
B. forefoot varus.
C. improper footwear.
D. running or jumping on hard or uneven surfaces.

QUESTION 2. Classic pathological findings of Achilles tendinosis include

A. inflammatory cell infiltrate.
B. thickened paratenon.
C. scattered neovascularization.
D. All of the above

QUESTION 3. A 40-year-old man feels a sudden, sharp pain in the back of his ankle while playing basketball. He reports a feeling of being kicked in the back of the leg and cannot walk off the court. What findings are likely to be present on exam?

A. Palpable defect in the Achilles tendon
B. Positive Thompson test
C. Inability to perform a single heel rise on the affected side
D. All of the above

QUESTION 4. The preceding patient elects nonoperative management. Which of the following are appropriate treatment options?

A. Peritendinous steroid injection
B. Brisement
C. Short-term casting with accelerated functional rehabilitation
D. Pain control with NSAIDs, and custom orthotics to allow immediate weight bearing and therapy

Answer Key

QUESTION 1. Correct answer: **B** (see Pathophysiology)

QUESTION 2. Correct answer: **C** (see Pathophysiology)

QUESTION 3. Correct answer: **D** (see Clinical Presentation)

QUESTION 4. Correct answer: **C** (see Treatment)

NONOPERATIVE REHABILITATION OF ACHILLES TENDINOPATHY

Leslie C. Hair, PT, DSc, OCS, FAAOMPT, Michael D. Rosenthal, PT, DSc, SCS, ATC, James H. Flint, MD, LCDR, MC USN, and John-Paul H. Rue, MD, CDR, MC USN

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- Restoration of normal joint mobility
- Progressive increase in neuromuscular demands (strength, endurance, and power)
- Evaluation and management of impairments throughout the kinetic chain likely to contribute to Achilles tendinopathy
- The goal of rehabilitation of Achilles tendinopathy is a safe and complete return to preinjury level of activity.
- In order to achieve this goal, a multimodal treatment approach is used. This approach focuses on restoration of mobility and muscular performance, not just isolated to the lower leg, but including the kinetic chain from the thoracolumbar region distally.
- Initiation of formal rehabilitation will vary depending upon the severity of tendinopathy at the time the athlete initiates care.
- However the milestones for management are the same whether care begins in the early acute, subacute, chronic, or acute on chronic stage.
- Milestones include normalization of talocrural and subtalar mobility, ability to perform single leg heel raises and eccentric gastroc-soleus exercises without pain, and progressive return to activities requiring rapid stretch-shortening cycles (i.e., running and jumping).
- Progression from phase to phase is based on improvements in functional performance and reduction in pain, not a rigid timeline.

Phase I (weeks 2 to 4)

Protection

- If the athlete displays an antalgic or altered gait, a CAM walking boot or crutches may be used to offload forces through the injured area.

Management of Pain and Swelling

- Ice[1]
- Pulsed ultrasound[2]
- Low level laser therapy[3]
- Iontophoresis[3]
- Foot orthosis for correction of excessive pronation
- Heel lift to reduce strain on the Achilles tendon

Techniques for Progressive Increase in Range of Motion

- Initial treatment should include awareness of the athlete's fitness level and consideration of what cardiorespiratory training may be used to mitigate deconditioning.
- Popular conditioning exercises in this early stage of rehabilitation include swimming, non–weight-bearing pool jogging (if pain free), and the upper body ergo meter. Exercises for the sound leg, core musculature, and upper body should be incorporated along with cardiorespiratory training treatment to optimize the athlete's readiness for return to sport upon resolution of the Achilles tendinopathy.
- Restoration of range of motion (ROM) follows a thorough evaluation of talocrural and subtalar mobility.
- Additional ROM assessment of proximal (i.e., hip) or distal joints (i.e., first metatarsophalangeal joint) should also be included, particularly in patients with prior injury to these regions.

TIMELINE 38-1: **Nonoperative Rehabilitation of Achilles Tendinopathy**

PHASE I (weeks 2 to 4)	PHASE II (weeks 3 to 12)

• Manual therapy
• Soft tissue techniques
• Stretching
  • Static stretching and active stretching
• Static single leg balance
• Four-way ankle isometrics
  • Low intensity eccentric loading
• Strengthening—legs and core
	• Manual therapy
	• Soft tissue techniques
	• Stretching
	  • Static stretching and active stretching
	• Sensorimotor exercises
	  • Dynamic single leg balance exercises
	• Eccentric loading
	• Strengthening—legs and core
	• Open kinetic chain and closed kinetic chain exercises
	• Plyometrics—low intensity and volume
	• Functional exercise
	• Sport-specific exercise

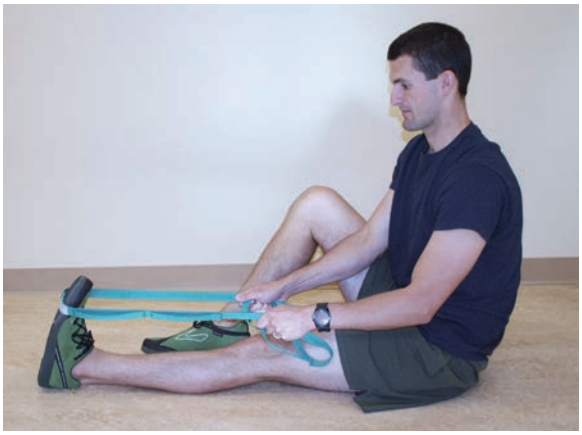

FIGURE 38-6. Strap assisted static stretch.

FIGURE 38-7. Active stretch performed with knee straight and knee slightly bent. The uninvolved side is "reaching" into the sagittal plane in a rhythmic manner.

- Muscular performance assessment will vary based upon the severity and irritability of the patient's condition.

Manual Therapy Techniques

- Identify mobility impairments through a manual exam of the foot and ankle. May use various techniques, including anteroposterior, posteroanterior, distraction, and translatory mobilization or manipulation to improve movement restrictions.

Soft Tissue Techniques

- The use of soft tissue mobilization (i.e., transverse friction massage, instrumented soft tissue mobilization) may be used to reduce pain and improve mobility. Utilization of these techniques in acute tendinopathy and paratendinitis is not recommended.[4]

Stretching/Flexibility Techniques for the Musculotendinous Unit

- Stretching exercises, to include the gastrocnemius and soleus muscle groups, may improve function in patients with dorsiflexion restrictions. Stretching should be performed with both static stretching (Figure 38-6) to restore normal musculotendinous extensibility (recommend comparison with the uninvolved limb), and by way of active and dynamic stretching (Figure 38-7).
- Static stretching performed two to three times daily with each set containing 5 to 10 repetitions and holding the stretch for 20 to 30 seconds. This type of stretching is incorporated into all phases of tendinopathy rehabilitation until symmetrical and pain free ROM about the ankle has been achieved.
- Active stretching performed for periods of 20 to 30 seconds, repeated for two to three sets, and repeated one to two times daily. Active stretching techniques will be implemented in all rehabilitation phases with the exception of the acute tendinopathy phase. Active stretching techniques will continue to be used once symmetry of ROM has been achieved and should be incorporated into the warmup portion of the rehabilitation and return to function phases.

TIMELINE 38-1 Nonoperative Rehabilitation of Achilles Tendinopathy (Continued)

PHASE III (weeks 12 to 36)	PHASE IV (weeks 16 to 52)

• Manual therapy
• Soft tissue techniques
• Stretching
  • Static, active, and dynamic stretching
• Total body strengthening
  • Olympic lifts
• Eccentric loading
• Strengthening—legs and core
• Sensorimotor exercises
• Open kinetic chain and closed kinetic chain exercises
• Plyometrics
• Functional exercise with reaction drills
• Sport-specific exercise with multiplanar and transitional movements
	• Manual therapy
	• Soft tissue techniques
	• Flexibility—calf and lower extremity
	  • Static, active, and dynamic stretching
	• Eccentric loading
	• Functional exercise
	• Sport-specific exercise
	• Transition to performance training
	• Sport-specific testing

FIGURE 38-8. Resistance band eccentric loading.

Other Therapeutic Exercises

- Eccentric loading
  - Two protocols are most frequently cited in the literature. Curwin and Stanish reported a program consisting of three sets of 10 repetitions and titrated by pain. This protocol included both concentric and eccentric muscle action. Increasing speed of the exercise was performed as part of the progression along with addition of light weight.[5] This program is recommended in Phase I for patients with acute tendinopathy. Initial loading may be induced by use of a resistance strap or band (Figure 38-8).
  - For those with chronic tendinopathy, the eccentric training program advocated by Alfredson is recommended.[6,7] Alfredson's protocol involves slow speed eccentric loading, exercising to the level of the athlete's pain, and includes the addition of greater loads as part of the exercise progression. The unaffected contralateral lower extremity returns the affected ankle to the starting position.
- Total leg strengthening to include the hip and thigh musculature
- Core strengthening exercises (i.e., side and front planks, pushups)
- Total lower extremity stretching to include the thigh, hip, and lumbosacral region

Activation of Primary Muscles Involved

- The posterior leg muscles, in particular the gastrocnemius and soleus, which join to form the Achilles tendon are the muscles targeted with the eccentric loading.

Sensorimotor Exercises

- Single leg balance exercises are introduced in this early phase of rehabilitation. Balance proprioception exercises progress from a firm to soft or unsteady surface.

Open and Closed Kinetic Chain Exercises

- Limited OKC exercises are incorporated. They include intrinsic foot muscle exercises to include towel/toe curls exercises and marble pickups. If the athlete is unable to tolerate weight bearing, OKC four-way (inversion, eversion, dorsiflexion, and plantarflexion) isometric or resistance band exercises may be utilized. CKC exercises include bridging with double leg support progress to single leg support.

Techniques to Increase Muscle Strength, Power, and Endurance

- Begin total lower extremity therapeutic exercise to include hip stabilization exercises; for example, hip abduction, gluteal strengthening, straight leg raises, and hamstring strengthening. This will include primarily CKC exercises of squatting (with varying base of support) (Figure 38-9*A,B*), dead lifts (double leg progressing to single leg), and lunges in the frontal plane in Phase I. Power and endurance components will be addressed by changes in the speed and/or duration of movement.

FIGURE 38-9. A,B, Squatting with differing bases of support imparts varying stress on the Achilles tendon and can help in transition to higher level, functional, and sport-specific activities.

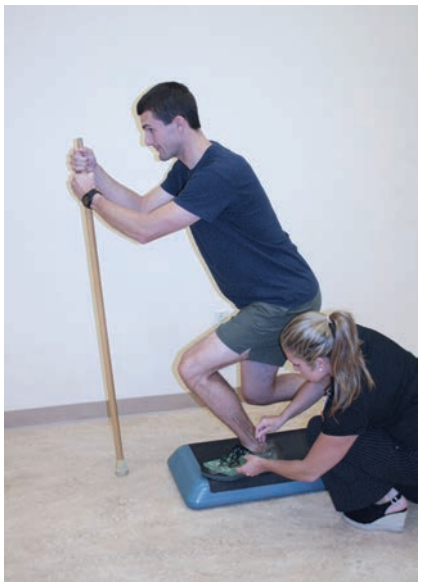

FIGURE 38-10. Closed kinetic chain assessment of dorsiflexion.

Milestones for Progression to the Next Phase

- Decreased pain
- Symmetry in lower extremity ROM: dorsiflexion measured in both the open and closed kinetic chain position (Figure 38-10)
- Normal gait

Phase II (weeks 3 to 12)

Clinical Pearl

Phase II involves a significant systematic increase in the dynamic stresses applied to the Achilles tendon. Ice application is not recommended prior to exercising because it increases tendon stiffness and the pain inhibition produced by icing may mask awareness of excessive exercise intensity.[5]

Management of Pain and Swelling

- Same as in Phase I.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Same as in Phase I.

Soft Tissue Techniques

- Same as in Phase I.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Static stretching will now be performed following cardiorespiratory and other rehabilitation exercises. The active stretching exercises will be a key focus of the warmup exercises before beginning higher level strengthening exercises.
- Static stretching performed one to two times daily with each set containing three to five repetitions and holding the stretch for 20 to 30 seconds.
- Active stretching techniques performed for periods of 20 to 30 seconds, repeated for two to three sets, and performed before higher level speed or resistance exercises to prepare the Achilles tendon for the increased loads.

Other Therapeutic Exercises

- Eccentric loading protocol (either the Curwin and Stanish or Alfredson protocol). Both protocols have been demonstrated to improve strength and function while decreasing pain in patients with midportion Achilles tendinopathy. Neither protocol has been proved superior.[8]
- Total leg strengthening exercises will now progress to include split squat exercises, double leg and single leg deadlifting, and sagittal plane lunges.
- Total spine and lower body stretching will continue throughout all phases of rehabilitation.

Sensorimotor Exercises

- Balance and proprioception exercises will incorporate sport- or activity-specific surfaces (i.e., basketball court, track surface, or gymnastics pad) and multiple planes of movement. Examples of exercises include the star excursion exercise or wall reach (Figure 38-11), which can include multiple angles/planes of movement. Exercise progression and promotion of tissue adaptation is accomplished by increasing the amplitude of movement (ROM), speed of movement (intensity), and volume of the activity (repetitions or duration of the exercise).

FIGURE 38-11. Wall reach. Reaching may be performed in the sagittal, frontal or transverse planes.

Open and Closed Kinetic Chain Exercises

- OKC exercises may include the use of isokinetic resistance exercises for dorsiflexion, plantarflexion, inversion and eversion. Although the focus is on progression of the more functional CKC exercises, such as squats and lunges mentioned previously in this phase, OKC exercises promote strength and local muscular endurance gains.

Plyometrics

- Gravity or weight bearing reduced plyometric exercises may be initiated during this phase. Examples include jumping or hopping in a pool, or using a gravity-reduced device (i.e., Total Gym or Shuttle Systems equipment). Plyometric volume should initially be very low and measured by foot contacts. Initial plyometric volume in the injured athlete should not exceed 30 foot contacts per workout with two to three workouts per week.

Functional Exercises

- Incorporate functional exercises such as squats, lunges, side lunges, and stepups into the total lower extremity strengthening routine.

Sport-Specific Exercises

- Form walking exercises (i.e., high knees with heel raise; Figure 38-12). Initiate sport-specific exercise into the routine for athletes. Start with low speed and low impact activities.

Milestones for Progression to the Next Phase

- Attainment of 5/5 strength of lower extremity muscles found to be weak during the evaluation and subsequent rehabilitation
- Symmetrical single leg squat and lunge

FIGURE 38-12. High knee walking with heel raise.

- Pain free heel raise × 15
- Pain free single leg hop × 5

Phase III (weeks 12 to 36)

Management of Pain and Swelling

- Same is in Phase I.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- See Phase II.

Soft Tissue Techniques

- See Phase II.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Static stretching should be performed one to two times daily with each set containing three to five repetitions and holding the stretch for 20 to 30 seconds.
- Active and dynamic stretching techniques should be performed for periods of 15 to 30 seconds, repeated for two to three sets.

Other Therapeutic Exercises

- Total body strengthening exercises during this phase include deadlifts, hang cleans or power cleans, and push-presses.

Activation of Primary Muscles Involved

- Although the gastrocnemius and soleus are the primary muscles involved, effective return to athletics requires the synergistic activation of trunk and lower extremity muscles.

Sensorimotor Exercises

- Further progression of exercises from Phase II with increasing amplitude of movement (ROM), speed of movement (intensity), and volume of activity (repetitions or duration of the exercise).

Techniques to Increase Muscle Strength, Power, and Endurance

- Closed kinetic chain exercises are primarily used for increasing muscular strength, power, and endurance in the final phase. Exercise selection progresses from basic exercises (i.e., squats to squat jumps to weighted squat jumps) to sport specific exercises (i.e., static single leg hops to high skipping to bounding).

Plyometrics

- Final stage plyometrics include progression to full weight bearing plyometrics and a gradual increase in

training volume and intensity. Progression involves counter movement jumps (double leg advancing to single leg) and box jumps (progressing in box height). Plyometric volume gradually increases to 40 to 80 repetitions. Athletes whose sport includes high volume and high intensity demands may approach 120 to 200 foot contacts no more than twice weekly.[9]

Functional Exercises

- Multidirectional and transitional movement (i.e., anterolateral to posteromedial lunging)
- Reaction drills (i.e., change of direction movements; forward, lateral, jump).
- Walk-jog progression

Sport-Specific Exercises

- Selection is based upon demand/needs analysis of the athlete's sport or functional impairment.
  - Progressive increase from jogging to sprinting
  - Agility drills (e.g., figure-eight runs, T-drills)
  - Run and jump repeats
  - Line drills

Milestones for Progression to the Next Phase

- Countermovement jumping without symptoms
- Run without symptoms

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention (weeks 16 to 52)

- Inability to regain strength
- Inability to regain function
- Debilitating pain
- Patient preference

Milestones/Criterion-Based Rehabilitation Guidelines to Progress to Advance Sport-Specific Training and Conditioning

- Greater than 75% symmetry in hop testing
  - May include SL hop for distance, SL vertical jump, SL triple hop, and box jumps
- Symmetry with single leg heel raise endurance test (maximum repetitions)

Tips and Guidelines for Transitioning to Performance Enhancement

- The transition to performance enhancement involves the inclusion of both sport-specific activities as well as continued variety of training stimulus (modes of training) and application of training variables (amplitude of movement, speed of movement, duration of activity/volume, and frequency of training stimulus).
- Although this program involves a progression of each component of athleticism (e.g., mobility, strength, power, endurance), the transition to performance enhancement and return to sport should involve a careful manipulation of variables and incorporate an undulating periodization model.
- This model enables effective upregulation of certain training variables while down-regulating other training components.

Performance Enhancement and Beyond Rehabilitation: Training/Trainer and Optimization of Athletic Performance

- Integration of training/sport-specific variables is required in the training "bridge" from rehabilitation to performance enhancement.
- This analysis should include all variables of the athlete's chosen sport. For example, the sport surface (i.e., court, field), frequency of training and competition, and rest-work cycles during practice and competition.
- Additionally, if the athlete's onset of symptoms was nontraumatic, a comprehensive kinetic chain assessment should be included in the later phase of rehabilitation in hopes of identifying possible strength and/or mobility asymmetries that could be the underlying cause of the condition and increase the likelihood of injury recurrence.

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Greater than 85% symmetry in hop testing

Evidence

Alfredson H, et al: Heavy-load eccentric calf muscle training for the treatment of chronic Achilles tendinosis. *Am J Sports Med* 26:360–366, 1998.

This research article provides an overview of the treatment protocols for Achilles tendinosis. The article discusses treatment and its variables associated with proper rehabilitation progression. (Level II evidence)

Carcia CR, et al: Achilles pain, stiffness, and muscle power deficits: Achilles tendinitis. *J Orthop Sports Phys Ther* 40:A1–26, 2010.

This comprehensive review article provides a synopsis of the evidence basis for numerous components of the management of Achilles tendinopathy. The overview includes review of examination and intervention components and provides the level of evidence associated with each aspect. (Level II evidence)

Cook JL, et al: Achilles tendinopathy. *Man Ther* 7:121–130, 2002.

This review article provides a comprehensive review of the manual therapy management of Achilles tendinopathy. The overview includes a review of the intervention components. (Level V evidence)

Cook JL, Purdam CR: Rehabilitation of lower limb tendinopathies. *Clin Sports Med* 22:777–789, 2003.

This review article provides a comprehensive review of the lower extremity tendinopathies. The overview provides a concise review the myriad of treatment options and some of the research that has assessed efficacy of the interventions. (Level V evidence)

Khan K, Cook J: The painful nonrupture tendon: clinical aspects. *Clin Sports Med* 22:711–725, 2003.

This review article covers the spectrum of evaluation and treatment of tendon injuries to include lower and upper extremity conditions. (Level V evidence)

Mafi N, et al: Superior short-term results with eccentric calf muscle training compared to concentric training in a randomized prospective multicenter study on patients with chronic Achilles tendinosis. *Knee Surg Sports Traumatol Arthrosc* 9:42–47, 2001.

This study randomized patients with chronic noninsertional Achilles tendinosis to either eccentric or concentric calf muscle training groups. A significant increase in patient reported improvement was noted in the eccentric training group. (Level I evidence)

Mayer F, et al: Effects of short-term treatment strategies over 4 weeks in Achilles tendinopathy. *Br J Sports Med* 41:228–236, 2007.

This study randomized men with Achilles tendinopathy to one of three treatment groups (Control, orthoses, or physiotherapy). Following 4 weeks of therapy, both treatment groups were improved with comparable improvements between groups. (Level II evidence)

Wasielewski NJ, Kotsko KM: Does eccentric exercise reduce pain and improve strength in physical active adults with symptomatic lower extremity tendinosis? A systematic review. *J Ath Trng* 42:409–421, 2007.

This article reviewed 27 studies that were randomized controlled trials involving the treatment of Achilles or patellar tendinosis in adults that utilized eccentric exercise as one of the treatment components. (Level I evidence)

Multiple Choice Questions

QUESTION 1. The following training variable(s) are included in the eccentric training protocol described by Curwin and Stanish.

A. Only eccentric movement of the injured Achilles
B. Slow speed of eccentric movement
C. Performance with the knee bent and knee straight
D. Titration of training volume based upon pain

QUESTION 2. The following training variable(s) are included in the eccentric training protocol described by Alfredson.

A. Concentric movement on the side of the injured Achilles
B. High speed of eccentric movement
C. Gradually increasing training volume
D. Gradual increase in training resistance

QUESTION 3. The following modalities are appropriate for use with Achilles tendinopathy

A. Ultrasound
B. Low level laser therapy
C. Ice
D. There is limited evidence for use of modalities with Achilles tendinopathy and rehab should focus on restoring mobility and strength

QUESTION 4. Functional exercise and sport-specific exercise should begin in phase?

A. Phase 1 (weeks 1 to 2)
B. Phase 2 (weeks 3 to 12)
C. Phase 3 (weeks 12 to 36)
D. Phase 4 (weeks 16 to 52)

QUESTION 5. What criteria indicate a need for referral to the orthopedic surgeon and consideration of operative intervention?

A. Inability to regain strength
B. Inability to gain function
C. Debilitating pain
D. All of the above

Answer Key

QUESTION 1. Correct answer: **D** (see Phase I)

QUESTION 2. Correct answer: **D** (see Phase II)

QUESTION 3. Correct answer: **D** (see Phase I)

QUESTION 4. Correct answer: **B** (see Phase III)

QUESTION 5. Correct answer: **D** (see Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention)

POSTOPERATIVE REHABILITATION OF ACHILLES TENDINOPATHY

James H. Flint, MD, LCDR, MC USN, Michael D. Rosenthal, PT, DSc, SCS, ECS, ATC, CSCS, Charles E. Rainey, PT, DSc, DPT, OCS, SCS, CSCS, FAAOMPT, and John-Paul H. Rue, MD, CDR, MC USN

Indications for Surgical Treatment

- Failure of nonoperative measures, typically after at least 3 to 6 months[1–3]
- Patient preference

Brief Summary of Surgical Treatment

Major Surgical Steps

- Achilles paratenonitis
  - Choice of anesthesia, patient in prone position on well-padded table
  - Place tourniquet on affected extremity before rolling for ease of application
  - Posteromedial incision to avoid small saphenous vein and sural nerve
  - Full thickness incision through skin down to paratenon
  - Identify any thickened or fibrotic areas of the paratenon and excise. Lyse any adhesions to the underlying tendon. Avoid excising anteriorly to preserve the blood supply to the tendon.[3,4]
  - Close the incision and dress the wound.
  - Postoperative splint or boot for edema control and soft tissue rest/wound healing
  - Rehabilitation should start as soon as the wound is sufficiently healed.
- Achilles tendinosis
  - For solitary, well-defined nodules less than 2.5 cm, percutaneous longitudinal tenotomies can be performed.
- May be performed in outpatient setting without use of tourniquet in some cases.[1,2]
- Rehabilitation can start (or continue) as soon as the stab incision(s) is sufficiently healed.

Clinical Pearl

When performing percutaneous tenotomy, ultrasound guidance should be used to ensure precise placement of the scalpel within the affected portion of the tendon.[1,2]

- For larger, or multiple, nodules, or in cases of tendinosis with associated paratenonitis, an open procedure is performed.
  - The same operative setup and surgical approach is used as described in the preceding.
  - Paratenonitis is addressed as in the preceding, and attention is then turned to the tendon proper.
  - Intratendinous incisions are made as indicated over the nodular areas. Nodular tissue (degenerated tendon) is excised and the tendon is repaired side-to-side with a buried, absorbable suture.[1,2,4,5]
  - Close the remaining paratenon and skin in layers.
  - Dress the wound and place the patient in a short-leg splint or removable boot.
  - The patient may bear weight fully and perform gentle range of motion, but formal rehabilitation should be postponed until the wound is sufficiently healed.

Factors That May Affect Rehabilitation

Anesthetic

- As indicated, patients may benefit from short-term narcotic analgesia. Be aware of the patient's pain medication needs and tailor accordingly.

Surgical

- Degree of tendinosis and/or paratenonitis
  - More advanced cases, which involve open procedures, need more time to recover and heal postoperatively when compared with simpler cases that may be addressed with percutaneous procedures.
- Size of exposure
  - More extensive debridement may require more extensive surgical incisions. Rehabilitation should not impede sufficient wound healing. Soft tissue healing takes precedence over initiation of aggressive rehabilitation.
- Quality of the tendon
  - For patients with severe tendinosis, with or without paratenonitis, consider allowing more time for soft tissue healing before starting aggressive rehabilitation.

Other Surgical Techniques and Options

- Endoscopic debridement[2]
- Advanced options (for patients with greater than 50% to 75% tendon degeneration)
  - Tendon transfers[3]
- For example, FDL, FHL
  - Allograft tendon reconstruction[3]

Before Surgery: Overview of Goals, Milestones, and Guidelines[1]

Guiding Principles of Postoperative Rehabilitation

- Understanding the stages of soft tissue healing and anatomic structures involved.

[1]*Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

- Application of appropriate levels of physical stress to the healing soft tissue to promote optimal recovery.
- Development of a systematic approach to soft tissue overload with the long-range goal in mind.
- Effective patient education on the comprehensive rehabilitation program.

Phase I (days 0 to 14): Immediate Postoperative Period

Clinical Pearl

Gentle non–weight-bearing motion should commence immediately. Active ROM and passive dorsiflexion with resistance band or stretch strap should be performed throughout the day. Active plantarflexion is allowed immediately.

Goals

- Protection of repaired structures
- Decrease pain and inflammation
- Prevent effects of immobilization

Protection

- Padded splint with the ankle in neutral dorsiflexion (DF).
- Crutch-assisted ambulation for the first 10 to 14 days.

Management of Pain and Swelling

Treatment for Pain/Analgesia

- Oral pain medications
- Cryotherapy to reduce pain and inflammation.
- Therapeutic modalities such as TENS and IFC e-stim.

Decrease Swelling

- Cryotherapy to reduce swelling
- Elevation of surgical limb

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Talocrural, subtalar, and mid-foot joint mobilizations

Soft Tissue Techniques

- Achilles tendon soft tissue mobilizations
- Scar mobilization to region of incision once closed
- Stretching/flexibility techniques for the musculotendinous unit
- Towel gastroc-soleus stretch (pain free)
- Ankle AROM (ABCs)

Other Therapeutic Exercises

- Straight leg raises
- May perform upper body and core exercises not requiring support of the involved lower extremity.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Resistance band exercises—dorsiflexion (DF), plantarflexion (PF), inversion (INV), and eversion (EV)
- Four-way ankle isometrics
- Seated heel (PF) and toe (DF) raises

Sensorimotor Exercises

- BAPS board (seated)

Milestones for Progression to the Next Phase

Performs all Phase I rehabilitation exercises without pain or increase in swelling

Phase II (weeks 2 to 6)

Clinical Pearl

Removable walking boot with adjustable heel is used for weeks 2 to 4. At week 2, weight bearing without crutches is allowed in the walking boot. Stationary bike is allowed when the patient tolerates full weight bearing. Discontinue walking boot at weeks 4 to 6.

Goals

- Protection of repaired structures
- Decrease in pain and inflammation

TIMELINE 38-2: **Postoperative Rehabilitation of Achilles Tendinopathy**

PHASE I (weeks 0 to 2)	PHASE II (weeks 3 to 6)	PHASE III (weeks 6 to 10)
• Splint (first 24 h) • Walking boot with crutches • DC crutches at week 2 • PROM for DF, PF, Inv, Ev • AROM ankle exercises (no active PF) • Joint mobilizations • Seated BAPS	• Walking boot • Aqua jogging • Stationary bike • AROM for all ankle motions • Seated heel/toe raises • Joint mobilizations • Scar mobilization	• D/C walking boot by week 6 • PREs for all ankle motions • Body weight squats and lunges • Standing eccentric gastroc-soleus • Gait training • Walking/jogging on trampoline • Mobilizations/flexibility as needed • Standing proprioceptive exercises • Begin walk/run progression at Week 8

- Discontinued use of crutches and walking boot
- Full weight-bearing status
- Normal ROM

Protection

- Use a walking boot for ambulation without crutches

Management of Pain and Swelling

- Same as Phase I

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Talocrural, subtalar, and mid-foot joint mobilizations

Soft Tissue Techniques

- Achilles tendon soft tissue mobilizations
- Scar mobilization to incision

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Towel calf stretch
- Ankle circles (ABCs)
- Ensure normal ROM in hip and knee and address any restrictions during this period.

Other Therapeutic Exercises

- Stationary bike
- Swimming and aqua jogging (wound healing must be complete)
- Straight leg raises
- Leg press, body weight squats

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Muscle activation of the gastroc-soleus complex during this second phase of rehabilitation begins with isometric plantar flexion and light resisted plantar flexion using a towel or resistance bands.

Techniques to Increase Muscle Strength, Power, and Endurance

- Lower body strengthening, including bodyweight squats, lunges, and wall sits; progressing to include leg press, step-up and step downs in the sagittal and frontal planes.

Functional Exercises

- Gait training from 3 to 6 weeks

Milestones for Progression to the Next Phase

- Full AROM
- Ambulates without assistance device

Phase III (weeks 6 to 10)

Goals

- Restore normal gait mechanics.
- 5/5 lower extremity strength
- Begin a walk-jog program.

Protection

- Walking boot discontinued

Management of Pain and Swelling

Treatment for Pain/Analgesia

- Cryotherapy
- Therapeutic modalities such as laser therapy and electrical stimulation as needed

Decrease Swelling

- Cryotherapy

Techniques for Progressive Increase in Range of Motion

- Same as in Phase II plus
  - Standing gastroc-soleus stretch (straight and bent knee)
  - Gastroc-soleus stretching using a slant board

Other Therapeutic Exercises

- Elliptical trainer
- Stairmaster

TIMELINE 38-2 **Postoperative Rehabilitation of Achilles Tendinopathy** (Continued)

PHASE IV (weeks 10 to 14)	PHASE V (weeks 14 to 24)	PHASE VI (weeks 24 to 52)
• Strength training • Single leg eccentric loading exercises • Olympic/power lifting • Running program progression • Begin agility and sport specific drills in controlled environment at week 12	• Running/sprint drills • Plyometrics • Agility and sport-specific drills (skipping → hopping → jumping) • Return to sport	• Individual strength and flexibility program based on impairments • Running/sprint drills • Plyometrics • Agility and sport-specific drills (skipping → hopping → jumping) • Return to sport

- Standing hip abduction
- Standing hamstring curls

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Resistance band exercises—dorsiflexion, plantarflexion, inversion, and eversion
- Sitting heel raises progressing to bilateral standing heel raises with slow eccentric lowering into maximal DF

Sensorimotor Exercises

- In-line tandem walking and lunging
- Single limb stance (with and without Airex pad)
- Rebounder exercises including ball toss and catch
- Hurdle step
- Standing BAPS

Techniques to Increase Muscle Strength, Power, and Endurance

- Progress from bodyweight squats and lunges to include increasing levels of resistance.
- Multi-planar lunges

Functional Exercises

- Gait training
- Form walking: high knees, lateral stepping, hurdle step overs/unders
- Walk to jog progression
- Stair climbing

Milestones for Progression to the Next Phase

- Normal gait
- Able to perform bilateral heel raises and lunges
- Symmetry in unilateral stance

Phase IV (weeks 10 to 14)

Goals

- Jogging 5 to 10 minutes
- Begin agility and sport-specific training

Therapeutic Exercises

- Outdoor biking
- Stair machine

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Single leg calf raises
- Eccentric loading (Figure 38-13*A*,*B*) protocol with technique as described by Alfredson[6]
- Progression of eccentric loading
- Week 10: 1 × 15 daily (qd)
- Week 11: 2 × 15 qd
- Week 12: 3 × 15 qd
- Week 13: 3 × 15 twice daily (bid) for 3 days and qd for 3 days
- Week 14: 3 × 15 bid

Sensorimotor Exercises

- Progression of Phase III exercises to include single leg balance and reach exercises (Figure 38-14*A*,*B*)

Techniques to Increase Muscle Strength, Power, and Endurance

- Gravity-reduced plyometrics (Figure 38-15)
- Deadlifts
- Single leg progressive resistance exercises:

FIGURE 38-13. A, Eccentric gastroc-soleus exercise with the starting ("up") position performed by the uninvolved lower extremity. **B,** Eccentric gastroc-soleus exercise at the finishing ("down") position. The lowering (eccentric) phase is performed with the bodyweight entirely supported by the involved lower extremity.

FIGURE 38-14. A, Sagittal plane balance and reach. **B,** Frontal plane balance and reach.

- Open kinetic chain quad and hamstring exercises
- Single leg squats
- Lunges or stepup/downs with weights

Plyometrics

- Lower extremity plyometric drills beginning in gravity reduced
- Skipping
- Line hops in sagittal and frontal plane

Functional Exercises

- Running drills
- Lateral shuffle

Sport-Specific Exercises

- Preplanned in controlled environment, such as cutting, lateral shuffles, jumping, hopping, change of directions while jogging

Milestones for Progression to the Next Phase

- Jog 5 to 10 minutes without pain
- Able to perform agility and sport specific drills

FIGURE 38-15. Reduced load plyometrics.

Outcome Measure

- Incorporation of patient reported outcome measures may include use of the Foot and Ankle Disability Index (FADI), Foot and Ankle Disability Index Sport, or Lower Extremity Functional Scale (LEFS)

Phase V (weeks 14 to 24)

Clinical Pearl

> Thorough performance evaluation of the athlete is important to ensure a safe and effective return to preinjury activity levels. Patient reported outcome measures should be greater than 90% and performance testing should demonstrate a limb symmetry index of greater than 85%.

Goals

- Sprint without symptoms
- Jump without symptoms
- Greater than 90% symmetry on performance testing

Therapeutic Exercises

- Olympic lifting (i.e., clean and jerk, snatch)
- Hang cleans or power cleans

Techniques to Increase Muscle Strength, Power, and Endurance

- Ongoing progressive resistance exercises may include squats, lunges, leg press, and stepups/downs.

Plyometrics

- Jump rope
- Box jumps

- Hopping and jumping in the sagittal, frontal, and transverse planes
- Bounding
- Tuck jumps

Functional Exercises

- Sprinting
- Change of direction drills
- Ladder drills

Sport-Specific Exercises

- Reactionary drills (i.e., change of direction in running in response to whistle, transition from running to jumping upon random signal).
- Sport specificity drills should include progression toward total work requirements of sport (duration, volume, and intensity of exercises).

Milestones for Progression to the Next Phase

- Performance of agility and sport specific drills without pain or movement asymmetry
- Limb symmetry index (LSI) of greater than 85% for hop testing
- LSI = Involved limb distance/uninvolved limb distance × 100

Phase VI (weeks 24 to 56)

Criteria for Return to Sport

General

- Athletes should be pain free and demonstrate symmetrical ROM and strength.
- Symmetry of gait with running, cutting, and pivoting movements
- Symmetry of LE jumping (unloading) and landing (loading)
- Hop tests may include any combination of the following and may be selected based upon specificity related to the athlete's sport. Single hop for distance, crossover triple hop for distance, triple hop for distance, and vertical jump should be at least 90% of the distance or height performed on the unaffected limb.

Sport-Specific

- For the athlete with demands for jumping observation of symmetry during jumping and landing should be conducted before sport, intermittently during the event, and then at the end of a simulated game/sport performance to assess for potential degradation of limb symmetry owing to fatigue.
- Needs analysis must be performed for any given sport. The rehab specialist should be able to determine the demands of the sport in question and determine optimal tests and exercises to ensure readiness for return to sport.

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Total body strengthening exercises, including lower extremity and core stability
- Plyometrics

Exercises and Other Techniques for Prevention of Recurrent Injury

- Maintenance of strength, mobility, and neuromuscular control/stability.
- Continuing sport specific training.
- Incorporation of effective training principles and caution with consecutive training days of increased training volume.

Evidence

Alfredson H, et al: Heavy-load eccentric calf muscle training for the treatment of chronic Achilles tendinosis. *Am J Sports Med* 26:360–366, 1998.

This prospective study applied a heavy-load eccentric training program versus conventional treatment to 15 recreational athletes (in each group) with chronic Achilles tendinosis. Following the 12-week program all patients in the eccentric training group had returned to preinjury levels of activity. None of the patients in the conventional treatment group returned to preinjury activity levels. (Level II evidence)

Bohu Y, Lefevre N, Bauer T, et al: Surgical treatment of Achilles tendinopathies in athletes. Multicenter retrospective series of open surgery and endoscopic techniques. *Orthop Traumatol Surg Res* 95:S72–S77, 2009.

A retrospective review of the literature with the aim of describing and analyzing surgical treatment of Achilles tendinopathy. (Level IV evidence)

Maffulli N, Kader D: Tendinopathy of tendo achillis. *J Bone Joint Surg Br* 84:1–8, 2002.

A review article discussing Achilles tendinopathy treatment focused on the body of the Achilles and not insertional region conditions. The article reviews tendon pathology, as well as conservative and operative management options with an extensive review of the available literature. (Level IV evidence)

Maffulli N, Longo UG, Denaro V: Novel approaches for the management of tendinopathy. *J Bone Joint Surg Am* 92:2604–2613, 2010.

Current concepts review of management options for Achilles tendinopathy. The article includes a discussion of the pathology along with operative and nonoperative management. The aim of operative treatment is discussed along with new operative procedures. Further research is advocated to evaluate best treatment options for optimal outcomes. (Level V evidence)

Reddy SS, Pedowitz DI, Parekh SG, et al: Surgical treatment for chronic disease and disorders of the achilles tendon. *J Am Acad Orthop Surg* 17:3–14, 2009.

A general overview of Achilles tendinopathy and rupture to include discussion of imaging options and spectrum of disease. A myriad of surgical options are presented with nonsurgical therapy recommended as the primary treatment for most patients. Long-term outcome studies were advocated to further guide treatment decisions. (Level V evidence)

Saltzman CL, Tearse DS: Achilles tendon injuries. *J Am Acad Orthop Surg* 6:316–325, 1998.

A general overview of Achilles tendinopathy and rupture. (Level V evidence)

Multiple Choice Questions

QUESTION 1. When is running allowed during the rehabilitation protocol?

A. Week 4 to 6
B. Week 6 to 8
C. Week 8 to 10
D. Week 10 to 12

QUESTION 2. When are agility and sport-specific training begun?

A. Week 8
B. Week 10
C. Week 12
D. Week 14

QUESTION 3. When is the walking boot discontinued?

A. Week 2 to 4
B. Week 4 to 6
C. Week 6 to 8
D. Week 8 to 10

QUESTION 4. In what ROM position is the ankle placed for the postoperative splint?

A. 20° of plantarflexion
B. 10° of plantarflexion
C. Neutral ankle position
D. 10° of dorsiflexion

QUESTION 5. How much tendon degeneration is typically involved before a surgeon would strongly consider advanced surgical techniques such as tendon transfer?

A. 0% to 15%
B. 15% to 25%
C. 25% to 50%
D. 50% to 75%

Answer Key

QUESTION 1. Correct answer: **B** (see Week 6 to 8)

QUESTION 2. Correct answer: **C** (see Week 10 to 14)

QUESTION 3. Correct answer: **A** (see Week 2 to 6)

QUESTION 4. Correct answer: **C** (see First 14 Days)

QUESTION 5. Correct answer: **D** (see Surgical Technique)

NONOPERATIVE REHABILITATION OF ACHILLES TENDON RUPTURE

Bradley Wells, PT, DPT, Michael D. Rosenthal, PT, DSc, SCS, ECS, ATC, CSCS, James H. Flint, MD, LCDR, MC USN, and John-Paul H. Rue, MD, CDR, MC USN

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION[3]

- Initial immobilization into 20° PF to promote approximation of ruptured tendon
- Patient casted in 20° PF for initial 10 days and is NWB using crutches
- Early mobilization with AROM DF to neutral and PROM PF
- No DF beyond neutral until week 4.
- Rehabilitation of Achilles tendon rupture is directed toward a safe and complete return to preinjury levels of activity.
- Attainment of these goals necessitates soft tissue approximation along with restoration of mobility and strength.
- Recent reviews of operative and nonoperative management have suggested that operative treatment results in better functional outcomes and reduced incidence of rerupture.[1,2]
- However more recent publications have reported comparable functional outcomes between operative and nonoperative treatment groups when early and functional rehabilitation is implemented.[3–6]

Phase I (days 10 to weeks 4)

Protection

- Plantar flexion (PF) cast is discontinued between 10 and 14 days
- Patient placed in removable orthosis with 20° PF
- Non–weight bearing (NWB) using bilateral crutches

Techniques for Progressive Increase in Range of Motion

- Early mobilization performed once every hour with emphasis being on no dorsiflexion (DF) past neutral
- AROM: DF to neutral
- PROM: PF as tolerated

Milestones for Progression to the Next Phase

- Maintenance of soft tissue approximation
- DF to, but not exceeding, neutral

Phase II (weeks 4 to 6)

Protection

- Removable orthosis brought to neutral
- Continued NWB ambulation with use of bilateral crutches

Management of Pain and Swelling

- Rest, ice, compression, elevation, and pain medication as indicated

Techniques for Progressive Increase in Range of Motion

Soft Tissue Techniques

- Gentle soft tissue/cross-friction massage to affected area of tendon
- ROM
  - Mobilization performed once every 2 to 4 hours with emphasis on:
    - AROM: DF not to exceed neutral
    - PROM: PF as tolerated

Other Therapeutic Exercises

- Strengthening of the proximal lower extremity muscles
  - Straight leg raises, open kinetic chain knee extension and flexion
- Strengthening exercises for unaffected lower extremity (LE) can be performed as long as affected LE remains NWB

Activation of Primary Muscles Involved

- Submaximal isometric muscle contraction of the posterior lower leg musculature and affected Achilles tendon is permissible in the PF cast and orthosis. Muscles involved include the gastrocnemius and soleus.

Clinical Pearl

The rehabilitation specialist must closely monitor restoration of DF mobility to prevent overzealous return of mobility. The possibility of excessive DF and unwarranted lengthening of the healing Achilles results in poor muscular function in the later stages of rehabilitation and suboptimal outcome.[7] Essential to this surveillance is effective education of the athlete regarding this topic.

Phase III (weeks 6 to 8)

Protection

- Weight-bearing as tolerated (WBAT) in orthosis with heel lift of 2 to 3 cm.

Management of Pain and Swelling

- Rest, ice, compression, elevation, pain medication as indicated
- Electrical stimulation

TIMELINE 38-3: **Nonoperative Rehabilitation for Acute Achilles Tendon Rupture**

Phase I (weeks 0 to 4)		PHASE II (weeks 4 to 6)	PHASE III (weeks 6 to 8)
Day 0–10	Day 10-Week 4		
• Cast in 20° PF • NWB using crutches	• D/C PF cast Apply removable orthosis set to 20° PF • Every hour-AROM DF not to exceed neutral and PROM PF	• Removable orthosis brought to neutral • Gentle soft tissue mobilization • Gentle gastroc/soleus isometrics • SLRs, OKC knee extensions and flexion • Well leg exercises	• WBAT in orthosis with 2- to 3-cm heel lift • Gait training on level surface in orthosis • Joint mobilizations • Balance and proprioceptive training in orthosis • DF AROM not to exceed 10° • Begin pool therapy: Walk → run in full emersion • Stationary bike in orthosis • CKC exercises in orthosis: squats, leg press with DF to neutral

Techniques for Progressive Increase in Range of Motion

Range of Motion

- Mobilization performed once every 3 to 4 hours with emphasis on:
  - AROM: DF not to exceed 10°
  - PROM: PF as tolerated

Manual Therapy Techniques

- Posterior and anterior ankle mobilizations of the talus on tibia.
- Medial and lateral subtalar joint mobilizations

Soft Tissue Techniques

- Soft tissue massage may include instrumented soft tissue mobilization techniques and cross friction massage to affected Achilles tendon.

Stretching/Flexibility Techniques for the Musculotendinous Unit

- Begin gentle DF stretching not to exceed 10°. Stretching should begin in the open kinetic chain mode and progress to include closed kinetic chain stretching.
- AAROM and AROM exercises are initiated for plantar flexion, inversion, and eversion.

Other Therapeutic Exercises

- Total leg strength exercises: static lunge with involved leg forward, wall squats or leg press with control of CKC DF to neutral
- Core stability exercises: front plank with pain-free stress on the involved LE and side planks
- Initiation of isolated strengthening of the gastroc-soleus complex with gentle resistance band plantarflexion exercise

Sensorimotor Exercises

- While in the orthosis the athlete may begin weight shift exercises progressing toward single leg balance as long as there is no Achilles pain.

Open and Closed Kinetic Chain Exercises

- OKC exercises to include straight-leg raises (SLRs), knee extension, and knee flexion.

FIGURE 38-16. Gravity reduced, dorsiflexion limited, squats.

- CKC exercises may include gravity reduced squats (Figure 38-16) progressing to wall squats and leg press. DF should not exceed neutral during performance of these exercises

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- AROM: DF 10°, PF, eversion, inversion normal
- Pain free full weight-bearing

Phase II (weeks 8 to 12)

Protection

- Discontinue orthosis
- Patient permitted full weight bearing
- Patient is permitted to wear normal shoes with heel lift of 1 cm if needed.

Management of Pain and Swelling

- Same as Phase III

TIMELINE 38-3 Nonoperative Rehabilitation for Acute Achilles Tendon Rupture (Continued)

PHASE IV (weeks 8 to 12)	PHASE V (weeks 12 to 16)	PHASE VI (weeks 16 to 24)
• Remove Orthosis, 1 cm heel lift as needed • Seated heel/toe raises • OKC PF with resistance bands • CKC exercises: step ups → step downs • Proprioceptive training: double leg → single leg balance drills • Gait training on treadmill level surface → gentle incline • Stationary bike • Pool therapy: Double leg toe raise → single leg	• Squats, lunges, leg press, lunges, leg press • Pool therapy: gentle jogging and hopping-start in chest deep water → waist deep	• Olympic/power lifting • Plyometrics • Walk-jog progression • Screening for return to sports and implementation/progression of sport-specific exercises

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Gradual progression of DF stretching in both OKC and CKC. DF ROM should gradually improve and not exceed the uninvolved LE.

Other Therapeutic Exercises

- Total leg strength exercises: deadlift, straight leg deadlifts

Activation of Primary Muscles Involved

- Seated heel and toe raises (Figure 38-17*A,B*)
- Bilateral heel raises starting with the majority of weight on the uninvolved leg and progressing to increase work performed by the involved LE.
- Low level eccentric muscle strengthening of the gastrocsoleus complex may be initiated in an OKC manner. Patient to perform active PF with minimal resistance, apply eccentric force with belt or strap and allow gradual movement into available end range of DF.

Sensorimotor Exercises

- Frontal and sagittal plane weight shifting from double leg stance to single leg stance. Progression of sensorimotor training will include changing the support surface (i.e., foam, wobble board), altering visual input (i.e., eyes open, eyes closed), and adding movement of the UE or uninvolved LE in the sagittal, frontal, or transverse planes.

Open and Closed Kinetic Chain Exercises

- Progression of Phase III exercises by increasing the amount of resistance and amplitude (ROM) of movement with DF beyond neutral.
- Additional CKC exercises: step ups, step downs, progression of heel rise to single leg toward the end of Phase IV

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention

- Failure of tendon ends at rupture site to approximate within 10 mm with ankle in neutral position.[7]
- Failure of tendon ends to completely approximate in 20° of ankle PF.[7]
- Surgical intervention may be suggested if rerupture occurs after nonoperative management.

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- Full ankle ROM in OKC and CKC
- Patient able to perform single leg heel rise
- 5/5 strength of proximal LE muscle
- Normal gait

Phase II (weeks 12 to 16)

Management of Pain and Swelling

- Same as Phase III

Therapeutic Exercises

- Total leg strength exercises: squats, lunges, leg press
- Core exercises: wood chopper, diagonal chop and lift pattern (Figure 38-18*A,B*)
- Pool therapy: form walking (high knees with heel rise), jogging, and jumping progressing to hopping (chest deep water progressing to waist deep water)

FIGURE 38-17. A, Seated heel raise. **B,** Seated toe raise.

FIGURE 38-18. A, Diagonal chop. **B,** Diagonal lift.

Plyometrics

- At week 12 jogging and hopping exercises are initiated in the pool. At week 16 a ground based return to running program and gravity reduced plyometrics (Figure 38-19) may be initiated if the patient is able to perform 10 to 15 single leg heel rises without pain.

Phase VI (weeks 16 to 24)

Management of Pain and Swelling

- Same as Phase III

Therapeutic Exercises

- Total leg strength exercises: front squats and multi-directional lunges
- Total body strengthening: deadlifts, hang cleans, power cleans

FIGURE 38-19. Gravity reduced plyometrics.

Plyometrics

- Begin dry land jumping and observe for symmetry of loading/unloading and monitor the athlete's response. Plyometric volume will begin at 20 to 30 foot contacts twice weekly from weeks 16 to 20. Foot contacts may increase from 20 to 50 foot contacts per workout with two to four sessions per week during weeks 20 to 24.[8,9]
- Jumping drills should include sagittal, frontal, and transverse plane movements.

Running Progression

- Walk-jog progression for weeks 16 to 20 with emphasis on increasing duration or volume of running, 2 to 3 days per week.
- Weeks 21 to 24: Begin to focus on increasing the speed of running. Continue with running 2 to 3 days per week.

Tips and Guidelines for Transitioning to Performance Enhancement

- Transition to performance enhancement begins when the athlete is able to demonstrate normal running gait, pain free jumping/hopping capability, and expresses readiness and desire to advance.
- An athlete's fear of injury in returning to higher level activities should be questioned and addressed before initiation of sports specific and performance enhancement training. Initiation of performance enhancement training should include progressing level of intensity and frequency of training.
- Additional progression should involve transition from preplanned movements/activities to react and respond drills.

Performance Enhancement and Beyond Rehabilitation: Training/ Trainer and Optimization of Athletic Performance

- Performance optimization requires thorough demand analysis of the athlete's sport in preparation for safe and effective return to preinjury levels of competition.
- Training will progress along the spectrum of functional demands to include increasing intensity (speed, resistance) of movements, volume (duration and frequency) of training, and specificity (i.e., drills, directions of movement, rest patterns).
- Recovery and active rest are also strategic components in program planning for return to sport.

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Single leg heel rise, symmetry of greater than 90% (number of repetitions to failure)
- Single leg hop for distance symmetry of greater than 90%
- Single leg vertical jump symmetry of greater than 90%
- Agility drills and hop tests performed without visual evidence of altered loading/unloading
- Athlete self-reported outcome measure of greater than 85%

Evidence

Hufner T, et al: Long-term results after functional nonoperative treatment of Achilles tendon rupture. *Foot Ankle Intl* 27:167–171, 2006.

This study reviewed the effectiveness of a treatment protocol for non-operative treatment of Achilles tendon rupture: 73.5% (N = 94) of patients were able to return to sport. The re-rupture rate was 6.4%. Strength was considered normal in 65.6% of patients. Nonoperative treatment achieved good results, but modifications to the treatment protocol were made at the conclusion of the study based on the results, including a repeat ultrasound 2 to 5 days after the first US to conclude nonoperative management is indicated, extending the use of 3-cm hindfoot elevation from 6 to 8 weeks, and then 1-cm hindfoot elevation in shoes for the following 3 months. (Level IV evidence)

Khan R, et al: Treatment of acute Achilles tendon ruptures: A meta-analysis of randomized, controlled trials. *J Bone Joint Surg* 87:2202–2210, 2005.

This meta-analysis included 12 trials involving 800 patients. Re-rupture occurred in 3.5% of patient treated operatively and 12.6% in patients treated nonoperatively. Complications besides re-rupture (infection, adhesions, decreased sensation) were found in 34.1% of operative patients versus 2.7% of nonoperative patients. It was also found that in those who suffered re-rupture, 2.4% were in a functional brace versus 12.2% who were casted. The authors concluded that operative management decreases the risk for re-rupture in Achilles tendon rupture repair patients but also raises the risk of other complications. (Level I evidence)

Nilsson-Helander K, et al: Acute Achilles tendon rupture: A randomized, controlled study comparing surgical and nonsurgical treatments using validated outcome measures. *Am J Sports Med* 38:2186–2193, 2010.

This study compared the 6- and 12-month outcomes in groups randomized to surgical versus conservative management. At 6 months the operative group performed superiorly on functional tests. At 12 months the surgical group was superior only in the heel rise work test. In both groups the functional performance on the injured limb was inferior to the uninjured limb at 12 months. (Level I evidence)

Twaddle B, et al: Early motion for Achilles tendon ruptures: Is surgery important? *Amer J Sports Med* 35:2033–2038, 2007.

This randomized prospective study placed 42 patients with acute Achilles tendon rupture in an operative or nonoperative group. Both groups received early motion in a removable orthosis and progressed to full weight-bearing in 8 weeks. Patients were followed over a 12-month period. There were no significant differences in plantarflexion, dorsiflexion, calf circumference, or MFAI scores. Early motion was deemed an acceptable form of rehabilitation for both surgically and nonsurgically treated patient who have suffered an acute Achilles tendon rupture. (Level I evidence)

Weber M, et al: Nonoperative treatment of acute rupture of the Achilles tendon: Results of a new protocol and comparison with operative treatment. *Amer J Sports Med* 31:685–691, 2003.

This retrospective cohort study compared 23 patients with acute Achilles tendon rupture treated nonoperatively with a equinus ankle cast and boot to 24 patients with the same injury who were treated operatively. Subsidence of pain, return to unaided walking, and return to work were faster for the nonoperative patients. Patient satisfaction, return to sports, and ultimate strength were found to be the same in both groups. The authors concluded that operative and nonoperative treatments for Achilles tendon rupture were equivalent. (Level II evidence)

Willits K, et al: Operative versus nonoperative treatment of acute Achilles tendon ruptures. *J Bone Joint Surg (Am)* 92:2767–2775, 2010.

This study randomized 144 patients and found better plantarflexion strength in the operative group at 1 year with other outcome measures demonstrating no significant differences. (Level I evidence)

Wong J, et al: Quantitative review of operative and nonoperative management of Achilles tendon ruptures. *Am J Sports Med* 30:565–575, 2002.

This review of 125 articles reported that re-rupture rates were greatest in the immobilized conservative management groups (10%) and skin healing complications highest in the open repair group and immobilization group (14.6%). It was noted that most articles had low quality of methodology and that a trend toward earlier mobilization was becoming apparent in the literature. Open repair and early mobilization was reported to provide the best outcomes. (Level I evidence)

Multiple Choice Questions

QUESTION 1. In the proposed treatment protocol for nonoperative management of acute Achilles tendon rupture, dorsiflexion beyond neutral should be avoided for _____ weeks.

A. 3
B. 4
C. 5
D. 6

QUESTION 2. During Phase I, the patient should remain in a removable orthosis set at _____ degrees of plantar flexion.

A. 10
B. 15
C. 20
D. 30

QUESTION 3. Gentle gastroc/soleus isometrics can be initiated during which phase of rehabilitation?

A. I
B. II
C. III
D. IV

QUESTION 4. During Phase III, which weight bearing status is recommended?

A. Full weight bearing (FWB)
B. Toe touch weight bearing (TTWB)
C. Non–weight bearing (NWB)
D. Weight bearing as tolerated (WBAT)

QUESTION 5. Return to running may begin during week _____ if the patient is symptom free.

A. 16
B. 12
C. 20
D. 23

Answer Key

QUESTION 1. Correct answer: **B** (see Box A: Guiding Principles of Rehabilitation)

QUESTION 2. Correct answer: **C** (see Phase I)

QUESTION 3. Correct answer: **B** (see Phase II)

QUESTION 4. Correct answer: **D** (see Phase III)

QUESTION 5. Correct answer: **A** (see Phase IV or Rehabilitation Timeline)

POSTOPERATIVE REHABILITATION OF ACHILLES TENDON RUPTURE

James H. Flint, MD, LCDR, MC USN, Michael D. Rosenthal, PT, DSc, SCS, ECS, ATC, CSCS, Charles E. Rainey, PT, DSc, DPT, OCS, SCS, CSCS, FAAOMPT, and John-Paul H. Rue, MD, CDR, MC USN

Indications for Surgical Treatment

- Failure of nonoperative measures, particularly in elite athletes who desire better functional performance and decreased rate of re-rupture[1–6]
- Patient preference

Brief Summary of Surgical Treatment

Major Surgical Steps

- Choice of anesthesia, patient in prone position on well-padded table
- Place tourniquet on affected extremity before rolling, consider bilateral prep to allow direct comparison of resting posture and tone presurgical and postsurgical repair
- Posteromedial incision to avoid small saphenous vein and sural nerve (Figure 38-20)
- Full-thickness incision through skin and paratenon directly down to tendon fibers
- Identify ragged edges proximal and distally ("mop ends") and judiciously trim back to more organized tissue (Figure 38-21).
- Suture the free ends using heavy, nonabsorbable suture; various techniques have been described and

FIGURE 38-20. A posteromedial incision is made to avoid the sural nerve and small saphenous vein. The length of incision will vary to allow optimal exposure and access to the tendon.

FIGURE 38-21. Exposed "mop-ends"; these will need to be trimmed judiciously to allow a cleaner, more organized, repair.

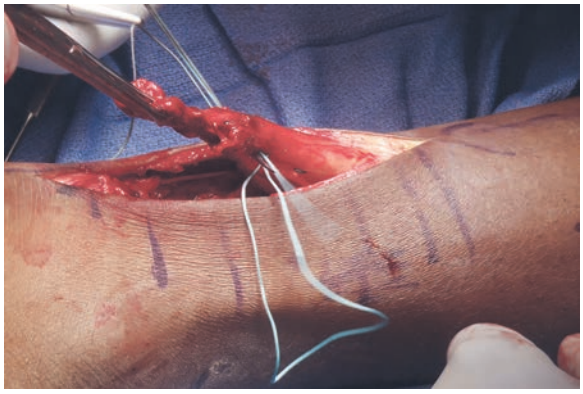

FIGURE 38-22. Various suture techniques are described. The Bunnell stitch was used in this case.

modifications exist (i.e., Bunnell, Kessler, Krackow)[5] (Figure 38-22).

- Once the tendon is repaired, ensure the foot does not fall into dorsiflexion.
- Close the paratenon and skin in layers (Figures 38-23 and 38-24).
- Dress the wound, place the patient in a short-leg splint in resting plantar-flexion (Figure 38-25).

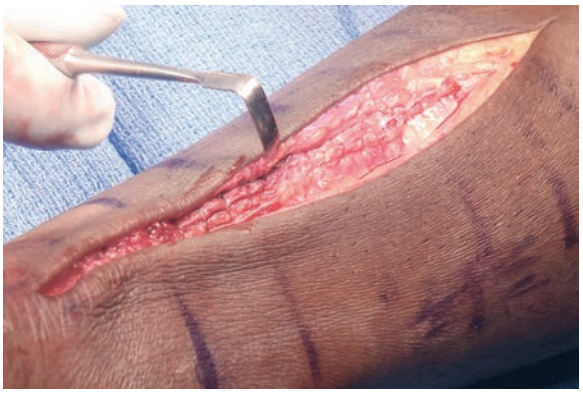

FIGURE 38-23. The paratenon is carefully preserved and reclosed with absorbable suture.

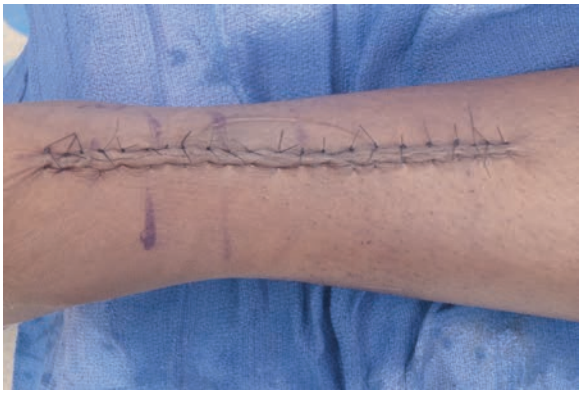

FIGURE 38-24. Various methods of skin-closure exist. Interrupted sutures allow equal tensioning of the skin, easy removal, and allows the surgeon to remove some sutures while leaving others in place (helpful when encountering skin healing issues)

FIGURE 38-25. A sterile dressing is applied and the ankle is secured in a plaster splint, with the ankle is resting plantar-flexion to protect the repair.

Factors That May Affect Rehabilitation

Anesthetic

- As indicated, patients may benefit from short-term narcotic analgesia. Be aware of the patient's pain medication needs and tailor accordingly.

Surgical

- Size of exposure
  - More extensive repairs require more extensive surgical incisions. Rehabilitation should not impede sufficient wound healing; stable soft tissue healing is necessary before aggressive rehabilitation.
- Amount of tendon retraction
  - If tendon edges were retracted and extensive plantarflexion, or advanced surgical techniques were required for repair (see the following), more time will need to be spent on recovering range of motion before aggressive rehabilitation.
- Quality of the tendon
  - For patients with underlying tendinosis or otherwise compromised tissue, consider allowing more time for the repair to heal before starting aggressive rehabilitation.

Other Surgical Techniques and Options

- Percutaneous repair
  - Alternative to simple open repair, with comparable outcomes[2,4,8]
  - Various techniques described, with varying number of stab incisions or small transverse incisions performed, and similar suture patterns to open repair[2,4,8]
- Advanced repair options (for chronic rupture or tendon retraction greater than 3 cm)[5,9]
  - Gastrocnemius turn-down
  - V-Y advancement
  - Tendon transfers/augmentation
    - That is FDL, FHL

Before Surgery: Overview of Goals, Milestones, and Guidelines[2]

GUIDING PRINCIPLES OF POSTOPERATIVE REHABILITATION

- Understanding the type of surgical procedure and quality of the repair.
- Understanding the stages of healing and the anatomic structures involved.
- Employing a systematic approach to soft tissue loading to optimize recovery.

[2]*Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

Phase I (days 0 to 14): Immediate Postoperative Period

Clinical Pearl

Gentle non–weight-bearing motion may begin as early as postoperative day 1 in a motion restricted splint or brace. Passive and active ROM is limited to neutral dorsiflexion (DF), whereas there are no ROM limitations on gentle plantar flexion (PF), inversion (INV), or eversion (EV) during the first 6 weeks. Early return to DF ROM is likely to contribute to unwanted lengthening and tendon compliance, contributing to suboptimal outcomes.[10]

Goals

- Protect repaired Achilles tendon.
- Decrease pain and inflammation.
- Prevent effects of immobilization.

Protection

- Padded plantigrade splint is applied for first 24 to 96 hours (see Figure 38-25)
- Rigid walking boot with three heel wedges resulting in approximately 20° of equinus is applied after splint is discontinued.
- Weight bearing as tolerated on crutches with rigid walking boot.

Management of Pain and Swelling

Pain

- Oral pain medications
- Cryotherapy to reduce pain and inflammation.
- Therapeutic modalities such as TENS and IFC e-stim.

Swelling

- Cryotherapy to reduce swelling
- Elevation of surgical limb

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Grades I and II talocrural, subtalar, distal tibiofibular, and mid-foot joint mobilizations

Soft Tissue Techniques

- N/A until incision is healed.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Ankle circles (ABCs) with DF limited to neutral

Other Therapeutic Exercises

- Total leg strength: straight leg raises and side lying hip abduction

- Core stability: hook lying side planks, front planks on knees

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Three-way ankle isometrics: DF, inversion (INV), and eversion (EV)

Milestones for Progression to the Next Phase

- Able to perform Phase I exercises without pain or increase in swelling

Phase II (weeks 2 to 6)

Clinical Pearls

Rigid walking boot with heel lifts are used for 6 weeks. At week 2 to 4, ambulation occurs in full weight bearing using walking boot with two heel lifts without crutches. At week 4, remove one heel lift from walking boot. Discontinue crutches at week 2 to 4 and walking boot at week 6.

Goals

- Protection of repaired structures
- Decrease pain and inflammation
- Neutral DF ROM
- Discontinue use of crutches and walking boot
- Full weight-bearing status

Protection

- Use a walking boot for ambulation without crutches as tolerated

Management of Pain and Swelling

- Same as Phase I

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Grades I and II talocrural, subtalar, distal tibiofibular, and mid-foot joint mobilizations

Soft Tissue Techniques

- Achilles tendon soft tissue mobilizations
- Scar mobilizations to surgical incision

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Gentle towel calf stretch not to exceed neutral DF
- Ankle circles (ABCs)

Other Therapeutic Exercises

- Stationary bike with walking boot
- TLS as in Phase I. Add open kinetic chain (OKC) knee extension and flexion

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Resistance band exercises—DF, INV, and EV
- Four-way ankle isometrics
- Sitting calf (heel) raises beginning at week 5

Techniques to Increase Muscle Strength, Power, and Endurance

- Bodyweight squats and wall sits beginning at week 5 in walking boot

Neuromuscular Dynamic Stability Exercises

- Seated BAPS board

Milestones for Progression to the Next Phase

- Phase II exercises performed without pain or swelling
- Ambulates without assistance device

TIMELINE 38-4: **Postoperative Rehabilitation for Acute Achilles Tendon Rupture**

PHASE I (weeks 1 to 2)	PHASE II (weeks 3 to 6)	PHASE III (weeks 6 to 10)
• Splint (first 24 h) • Walking boot (three heel lifts) with crutches • PROM for DF not to exceed neutral • AROM ankle exercises (DF, EV, INV) • Joint mobilizations • Cryotherapy, e-stim	• Walking boot (two heel lifts) • DC crutches • Cryotherapy, E-stim • PROM for DF (not past neutral), PF, Inv, Ev • AROM for all ankle motions • Isometric and resistance band exercises • OKC PREs for knee and hip • Bodyweight squats, wall sits in boot • Stationary bike in boot • Joint mobilizations • Scar mobilization • Gait training with walking boot	• DC walking boot at week 6 • Wear shoes with one heel lift (D/C heel lift at week 8) • Resistance band exercises • Sitting heel raises • Stair climber • Aquatic therapy • Gait training • CKC Achilles stretch • Step ups • Bodyweight squat, lunges • Leg press • Single leg stance/balance exercises • Standing BAPS • Remove heel lift from shoes at week 8

Phase III (weeks 6 to 10)

Clinical Pearl

At week 6 the walking boot is discontinued. Ambulate in athletic shoes with one ¼- to ½-inch heel lift progressing to walking without a heel lift by week 8 to 10.

Goals

- Restore normal gait mechanics without heel lifts in shoes
- Full active ankle ROM

Protection

- Discontinue walking boot for ambulation

Management of Pain and Swelling

- Same as Phase I
- For swelling, cryotherapy as needed.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Grades II and III talocrural, subtalar, distal tibiofibular, and mid-foot joint mobilizations

Soft Tissue Techniques

- Achilles tendon soft tissue mobilizations

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Towel calf stretch
- Gentle standing calf stretch (straight and bent leg). DF should be compared with the uninvolved LE with education of avoidance of overstretching.

Other Therapeutic Exercises

- Stationary bike
- Aquatic therapy: swimming, gait training, deep water aqua jogging with floatation device/belt
- Stair climber[7,8]
- TLS: leg press, static lunges, step-ups, OKC hamstring curls and knee extensions

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Resistance band exercises—DF, PF, EV, INV
- Sitting heel raises progression to bilateral standing calf raises at week 7 to 8

Sensorimotor Exercises

- In-line tandem walking
- Single limb stance progression
- Standing BAPS
- Walking on mini-trampoline

Techniques to Increase Muscle Strength, Power, and Endurance

- Wall sits
- Step-up, lateral step up, and forward step down

Functional Exercises

- Gait training
- Stair climbing
- Backward walking on treadmill
- Side stepping using agility ladder or cones

Milestones for Progression to the Next Phase

- Perform Phase III exercises without pain or swelling
- Ambulate without heel lift
- Full ankle AROM
- Able to perform bilateral calf raises
- Symmetrical unilateral stance

TIMELINE 38-4 Postoperative Rehabilitation for Acute Achilles Tendon Rupture (Continued)

PHASE IV (weeks 10 to 14)	PHASE V (weeks 14 to 24)	PHASE VI (weeks 24 to 52)
• Elliptical trainer • Walk-jog progression • PREs for all motions • OKC eccentric Achilles loading • Bilateral standing heel raises • SL balance and reach • Patient reported outcome measures	• SL heel raises • SL squats • Jog progression to running/sprint drills • Form running drills • Plyometrics @ 20 wks • Olympic style lifts @ 20–24 wks • Agility and sport-specific drills • Hop testing • Patient-reported outcome measures	• Individual strength and flexibility program based off impairments • Running/sprint drills • Plyometrics • Agility and sport-specific drills (skipping → hopping → jumping) • Return to sport

Phase IV (weeks 10 to 14)

Clinical Pearl

Walk-jog progression may begin at 10 to 12 weeks. Initiation of jogging is contingent upon normal walking gait, full AROM, ability to perform bilateral concentric heel raising, and at least 4+/5 strength of all lower extremity muscle groups (except gastrocsoleus). Begin agility and sport specific drills at week 12 if athlete has been able to resume jogging.

Goals

- Restore normal gait mechanics.
- Continue lower chain strengthening.
- Begin jogging and agility training.

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Same as Phase III

Other Therapeutic Exercises

- Outdoor biking
- Elliptical trainer
- Stair machine
- TLS: deadlifts, squats, lunges
- Core stability: woodchopper, diagonal chop and lift patterns, front and side planks

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Seated progressing to standing single leg calf (heel) raises
- Eccentric Achilles loading exercises in non–weight bearing using a resistance band or stretch strap
- Bilateral standing calf (heel) raises

Sensorimotor Exercises

- Hurdle step over
- In-line lunges
- Single leg balance and reach in the sagittal plane, frontal plane, and diagonal patterns

Techniques to Increase Muscle Strength, Power, and Endurance

- Bodyweight squats and lunges, leg press.
- Lateral step-up/down, sagittal plane step-up/down

Plyometrics

- Form walking with high knees and heel raises

Functional Exercises

- Walk to jog progression
- Jogging to running drills

Sport-Specific Exercises

- Lower extremity drills in controlled environment, such as figure-eight jogging, side shuffles, and cutting (i.e., 45° change of direction)

Milestones for Progression to the Next Phase

- Perform Phase IV exercises without pain or swelling
- Able to perform concentric single leg heel raise
- Able to jog

Outcome Measure

- Patient reported outcome measures should be implemented at week 12. Outcome measures may include the Foot and Ankle Disability Index (FADI), Foot and Ankle Disability Index Sport, Lower Extremity Functional Scale (LEFS), and Achilles tendon Total Rupture Score (ATRS).

Phase V (weeks 14 to 24)

Clinical Pearl

Exercise progression in the final stages of rehabilitation should incorporate changes increases in amplitude of movement (ROM), rate of movement (speed), and volume (repetitions or time of activity). Additionally exercises should include transitioning from simple to more complex (multiplanar) movement patterns.

Goals

- Continue agility and sport specific training
- Continue lower extremity strengthening

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Same as Phase IV

Other Therapeutic Exercises

- Progression of Phase IV exercises

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Single leg calf raises
- Eccentric Achilles loading in bilateral stance progressing to single leg eccentric loading between weeks 20 to 24

Sensorimotor Exercises

- Progression of phase IV exercises

Techniques to Increase Muscle Strength, Power, and Endurance

- Olympic lifting techniques (i.e., push-press, cleans, snatches) may begin at around 20 weeks beginning with light weight.
- Single leg squats

Plyometrics

- Gravity reduced jumping (Figure 38-26)
- Skipping
- Line jumping (sagittal and frontal plane)
- Tuck jumps
- Box jump up with step-down progressing to jump up and jump off at week 20 to 24
- Single leg hopping in the frontal, sagittal, and transverse planes
- Bounding

Functional Exercises

- Form running drills
- Ladder drills
- Change of direction drills (i.e., forward to backward running)
- Increasing speed of jogging/running
- Outdoor running

Sport-Specific Exercises

- Lower extremity drills in controlled environment, such as cutting, side shuffles, jumping, hopping
- Reactionary drills (i.e., change of direction in running in response to whistle, transition from running to jumping upon random signal).
- Sport specificity drills should include progression toward total work requirements of sport (duration, volume, and intensity of exercises).

Milestones for Progression to the Next Phase

- Performance of Phase V activities without pain or swelling

FIGURE 38-26. Gravity reduced plyometric exercise.

- Performance of agility and sport specific drills without pain or movement asymmetry
- Limb symmetry index (LSI) of greater than 85% for hop testing.
  - LSI = Involved limb distance/uninvolved limb distance × 100
- Running gait without asymmetry
- Less than 10% side-to-side deficit on isokinetic testing

Phase VI (weeks 24 to 52)

Criteria for Return to Sport

General

- Athletes should be pain free and demonstrate symmetrical ROM and strength.
- Symmetry of gait with running, cutting, and pivoting movements
- Symmetry of LE jumping (unloading) and landing (loading).
- Hop tests may include any combination of the following and may be selected based upon specificity related to the athlete's sport. Single hop for distance, crossover triple hop for distance, triple hop for distance, and vertical jump should be at least 90% of the distance or height performed on the unaffected limb.

Sport-Specific

- Limb symmetry observed in the rested state does not guarantee acceptable symmetry throughout the performance of sport. Athletes should be closely monitored for asymmetrical limb performance during jumping, landing and running tasks upon returning to sport. Asymmetry of limb performance is likely to manifest with increasing levels of fatigue.
- American football and soccer athletes should be able to perform sport-specific performance testing (i.e., pro-agility run, T-drill, and on field maneuvers) with symmetry (no indication of favoring the involved LE).
- Needs analysis must be performed for any given sport. The rehabilitation specialist should be able to determine the demands of the sport in question and determine optimal tests and exercises to ensure readiness for return to sport.

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Total body strengthening exercises, including lower extremity and core stability
- Single leg eccentric Achilles training

Exercises and Other Techniques for Prevention of Recurrent Injury

- Prevent injury reoccurrence by maintaining strength, mobility, and neuromuscular control/stability.
- Continuing sport-specific training is recommended for optimal performance upon returning to sports.

Evidence

Bhandari M, Guyatt GH, Siddiqui F, et al: Treatment of acute Achilles tendon ruptures: A systematic overview and metaanalysis. *Clin Orthop Relat Res* 190–200, 2002.

A systematic review and metaanalysis of the literature to determine the effect of surgical versus conservative treamtent of acute Achilles tendon rupture. Surgical treatment was associated with a lower re-reputure rate, but higher risk of infection when compared with conservative therapy. (Level I evidence)

Gigante A, Moschini A, Verdenelli A, et al: Open versus percutaneous repair in the treatment of acute Achilles tendon rupture: A randomized prospective study. *Knee Surg Sports Traumatol Arthrosc* 16:204–209, 2008.

This prospective, randomized study of 40 patients compared open versus percutaneous Achilles tendon repair. At 12 months, Short Form-12 questionnaire, ultrasound scanning for tendon integrity, and isokinetic testing did not show significant differences between groups. (Level I evidence)

Henriquez H, Munoz R, Carcuro G, et al: Is percutaneous repair better than open repair in acute Achilles tendon rupture? *Clin Orthop Relat Res* 470(4):998–1003, 2012.

This retrospective review of 32 cases compared outcomes of patients treated with open versus percutaneous repair techniques. They conclude that percutaneous repair provides similar postoperative ROM and strength with no apparent difference in re-rupture rate, with better cosmesis and fewer wound complications. (Level III evidence)

Maffulli N, Longo UG, Maffulli GD, et al: Achilles tendon ruptures in elite athletes. *Foot Ankle Int* 32:9–15, 2011.

This retrospective case series of 17 patients evaluates outcomes after percutanous Achilles tendon repair in elite athletes. They report an average time to return to full sports of 4.8 ± 0.9 months and conclude that percutaneous repair is a good option for elite athletes. (Level IV evidence)

McCoy BW, Haddad SL: The strength of achilles tendon repair: A comparison of three suture techniques in human cadaver tendons. *Foot Ankle Int* 31:701–705, 2010.

This cadaveric study compares three suture repair techniques for Achilles tendon ruptures regarding strength; no significant difference was found.

Metz R, Verleisdonk EJ, van der Heijden GJ, et al: Acute Achilles tendon rupture: Minimally invasive surgery versus nonoperative treatment with immediate full weightbearing—a randomized controlled trial. *Am J Sports Med* 36:1688–1694, 2008.

This randomized controlled trial of 83 patients evaluates complications other than re-rupture in patients treated with minimally invasive surgery versus nonoperative treatment. They conclude that although a clinically important difference in the rate of complications exists, the data did not reach statistical significance. (Level II evidence)

Mullaney MJ, McHugh MP, Tyler TF, et al: Weakness in end-range plantar flexion after Achilles tendon repair. *Am J Sports Med* 34:1120–1125, 2006.

This study assessed plantar flexion strength and dorsiflexion stiffness following Achilles tendon repair in 20 patients. Passive joint stiffness was 34% lower on the involved side and plantarflexion weakness was 20% to 34% weaker. Additionally, nearly 75% of the patients were unable to perform a decline heel rise at follow up (average 1.8 years postoperative). (Level III evidence)

Reddy SS, Pedowitz DI, Parekh SG, et al: Surgical treatment for chronic disease and disorders of the achilles tendon. *J Am Acad Orthop Surg* 17:3–14, 2009.

A general overview of Achilles tendinopathy and rupture.

Rettig AC, Liotta FJ, Klootwyk TE, et al: Potential risk of rerupture in primary achilles tendon repair in athletes younger than 30 years of age. *Am J Sports Med* 33:119–123, 2005.

This retrospective review of 89 patients evaluated the risk of Achilles tendon rerupture in patients under 30 years old versus patients over 30. They observed four re-ruptures, for an overall rate of 4.5%. All of the re-ruptures occurred in the younger population, giving a re-rupture rate of 16.6% in patients less than 30 years old. They conclude that caution should be taken during rehabilitation of younger patients. (Level IV evidence)

Saltzman CL, Tearse DS: Achilles tendon injuries. *J Am Acad Orthop Surg* 6:316–325, 1998.

A general overview of Achilles tendinopathy and rupture.

Multiple Choice Questions

QUESTION 1. When is the earliest the walking boot can be discontinued?

A. Week 2
B. Week 4
C. Week 6
D. Week 8

QUESTION 2. When is agility and sport specific training begun?

A. Week 8
B. Week 10
C. Week 12
D. Week 14

QUESTION 3. When can running activities begin?

A. Week 6
B. Week 8
C. Week 10
D. Week 12

QUESTION 4. When is the patient able to ambulate in shoes without no heel lifts?

A. Week 6
B. Week 7
C. Week 8
D. Week 9

QUESTION 5. When performing an open repair for an acute Achilles tendon rupture, where do you make the incision to avoid inadvertent damage to the sural nerve?

A. Posterolateral
B. Posteromedial
C. Direct posterior
D. Transversely at the rupture site

QUESTION 6. How has surgical repair of the ruptured Achilles been demonstrated to be superior to conservative management?

A. Improved ROM
B. More rapid return to running
C. Fewer complications
D. Lower re-rupture rate

Answer Key

QUESTION 1. Correct answer: **C** (see Phase II)

QUESTION 2. Correct answer: **C** (see Phase IV)

QUESTION 3. Correct answer: **C** (see Phase IV)

QUESTION 4. Correct answer: **C** (see Phase III)

QUESTION 5. Correct answer: **B** (see Surgical Technique)

QUESTION 6. Correct answer: **D** (see Indications for Surgical Treatment)

BEYOND BASIC REHABILITATION: RETURN TO BASKETBALL AFTER TREATMENT OF ACHILLES TENDON RUPTURE

Bradley Wells, PT, DPT, Michael D. Rosenthal, PT, DSc, SCS, ECS, ATC, CSCS, James H. Flint, MD, LCDR, MC USN, and John-Paul H. Rue, MD, CDR, MC USN

Introduction

ASPECTS OF BASKETBALL THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- Jumping
- Running
- Pivoting/cutting
- Acceleration/deceleration movements

- Achilles tendon rupture secondary to athletic activity specifically racquet or ball sports has been noted in 75% to 80% of cases.[1,2]
- Achilles tendon ruptures are most common in sports, such as basketball, which require high power output and increased force production for activities such as running, jumping, and cutting.
- Studies report a high level of return to sport following Achilles rupture, deficits in strength and performance measures have been noted at 1 to 2 years following both surgical and conservative management.
- After an Achilles tendon rupture extensive rehabilitation is recommended to optimize return to function and sport.

Literature

- Mandelbaum et al. described an accelerated rehabilitation program for athletes who have incurred an Achilles tendon rupture.[3]
- It was found that by adhering to this accelerated program 93% of athletes returned to sports by 6 months with only small deficits (2% to 3%) of preinjury power and strength, and all patients (100%) returned to sports by 12 months.
- In this program passive range of motion (ROM) exercises begin 72 hours postoperatively, at 2 weeks ambulation in a walking boot was allowed, and full weight bearing began at 6 weeks.

Phase I: Advanced Strength and Conditioning Programs

Periodization

- Mesocycle: weeks 2 to 8

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Flexibility/joint mobility for joint stability

- Cardiorespiratory training
- Training for optimum muscle functional strength

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload

Application of Acute Training Variables

- Acute training variables include choice of exercises, order of exercises, amount of load, number of sets, performance speed of the exercise, magnitude of movement during the exercise (ROM), type of contraction, and rest period.
- During Phase I, exercises are limited and focus on gradual return of mobility and strength in the localized region of the injury/surgery, sustainment of mobility in strength in proximal joints, and limited cardiorespiratory training.
- Exercises include simple/isolated movement patterns progressing to integrated/complex movement integration toward the latter portion of Phase I.
- Speed and amplitude of movement will initially be slow with limited ROM, with both variables increasing throughout the training program.
- Phase I resistance exercises progress from isometrics to light concentric and eccentric loading with light loads.
- Repetitions are high, with a work-to-rest ratio of 1:1.
- Repetitions: 10 to 15
- Sets: two to four
- Rest interval: 1 to 3 minutes
- Intensity: low
- Repetition tempo: rate of repetitions is initially slow and progresses to moderate speed
- Training frequency: 2 to 4 days per week (allow 1 to 2 days recovery between sessions)
- Training duration: 30 to 60 minutes
- Training volume: total number of repetitions completed in training session will vary
- Specific exercises used in the training:
  - Four-way hip exercises (straight leg raises or resistance machine) beginning at week 2 to 3
  - Pool therapy:
    - Walking beginning at week 2 to 3
    - Double leg (DL) heel raises beginning at week 4 progressing to single leg (SL) heel raises in chest deep water at week 6
  - Isometric ankle inversion and eversion exercises beginning at week 3
  - Seated active dorsiflexion and plantar flexion exercises beginning at week 3
  - Resistance band inversion and eversion exercises at week 4
  - Pain-free WB DF at week 5
  - Gait training: In splint until week 5; out of splint at week 5
  - Standing DL heel raises at week 5
  - Stationary bike in splint until week 5, out of splint at week 5
  - Initiate submaximal isokinetic DF and PF focusing on endurance

Application of Chronic Training Variables

- Chronic training variable considerations include aerobic capacity, anaerobic capacity, strength, speed, agility, quickness, flexibility, and power.
- In this early stage low intensity cardiorespiratory training can be implemented.
- Flexibility and strength of the uninvolved joints should be maintained while the focus is on gradual increase of these two variables about the lower leg.
- Cardiorespiratory training.
  - Upper body ergometer beginning at week 1
  - Belt or vest suspended (deep water) pool walking and jogging beginning at week 2 to 3 for nonoperative management and when surgical incisions are well healed for postoperative management
- Appropriate response to manipulation of exercise variables may include localized musculotendinous soreness that resolves before increasing levels of tissue stress.

TIMELINE 38-5: **Return to Basketball after Achilles Tendon Rupture**

PHASE I (weeks 0 to 1)	PHASE II (weeks 2 to 8)

• PROM PF 10–20° progressing toward 5° PF
• Toe curls/spreads
• In splint when not performing PROM
• Elevation
• Ice
	• AROM ankle exercises: circles/ ABC's/ DF to PF limiting DF to neutral at 4 weeks 10° at 6 weeks, and symmetry at 8–10 weeks
	• Pain-free resisted ankle exercises beginning with isometrics and progressing to resistance bands
	• Gait training in splint
	• Stationary bike in splint
	• Resistance exercises for proximal LE muscle groups (4-way hip ex)
	• Upper body ergometer
	• Week 3: PROM (gentle) DF stretch with towel
	• Week 5:
	  • Weight-bearing CKC DF
	  • Gait training out of splint
	• Week 6:
	  • Double-leg toe raises
	  • Stationary bike without splint
	• Pool therapy: week 5: Double-leg → Single-leg toe raise in chest-deep water
	• Walk→ Run at full emersion (non–weight-bearing)

Phase II: Performance Enhancement Training Techniques

Periodization

- Mesocycle: weeks 8 to 20

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Flexibility/joint mobility for joint stability
- Core training
- Sensorimotor and balance training
- Multiplanar training activities
- Training for optimum muscle functional strength
- Training for optimum muscle functional power

Olympic Lifts Used in the Training Program

- Olympic lifts are not integrated until Phase III.

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload
- Principle of variation
- Principles of specificity: specific adaptation to imposed demands (SAID)

Application of Acute Training Variables

- During Phase II, now that the Achilles tendon is ready for weight bearing and increased loading, exercise options significantly expand and the focus is now on restoration of normal mobility, increase in strength, and progressive implementation of integrated movement patterns.
- Speed and amplitude of movement include slow and moderate speeds with increasing.
- Phase II resistance exercises include moderate intensity isometrics and light, progressing to moderate intensity concentric and eccentric loading with light loads.
- Repetitions per set are moderate, with a work to rest ratio increasing to 1:2 to 3 to promote neuromuscular recovery between sets.
- Research does not indicate a singular optimal approach to regaining strength and power. Most recently, eccentric training has been widely reported in the literature for restoration of optimal function following Achilles tendon injury.[4]
- When performing an eccentric contraction protocol Stanish et al. found that using three sets of 10 repetitions, worked well for building strength.[5]
- Alfredson et al. proposed an eccentric loading protocol of three sets of 15 repetitions conducted twice daily as long as the pain did not exceed the level of pain experienced with the exacerbating activity or sport.[4]
- The DeLorme program which was developed for resistance exercise and has been advocated in the use of rehabilitation uses three sets of 10 repetitions with a pyramid type design.[6] This program was developed in 1945 and is still used today for the rehabilitation of athletes and has been proved to strengthen muscle.
- Intensity should be kept to submaximal to allow the musculotendinous tissue to adapt to increased force demands while still healing.
- Strengthening exercise sessions should be separated by at least one full day to allow the muscle to fully heal from any breakdown caused by training.
- Repetitions: 8 to 12 repetitions per set
- Repetition tempo: combination of slow to moderate speed loading
- Sets: three to five
- Rest interval: at least 1 minute between sets
- Intensity: moderate, working to 80% of full strength by end of phase II
- Training frequency: three to four times per week (no consecutive days)
- Training duration: 30 to 60 minutes

TIMELINE 38-5 **Return to Basketball after Achilles Tendon Rupture** (Continued)

PHASE III (weeks 8 to 20)	PHASE IV (weeks 17 to 36)
• Continue with strengthening from previous phase for individual impairments • Submaximal isokinetics • Stationary biking, elliptical, rowing machine • Core training • Single leg balance exercises • Body weight strength training (squats/lunges) • Balance and reach exercised • Gait training on treadmill (Alter G): Level surface → Incline walking if symptom free • Treadmill jogging beginning at 12 weeks if good mobility and LE strength • Pool therapy: Gentle hopping → jumping in waist-deep water	• Individual strength and flexibility program based off impairments • Return to Running Program if symptom free • Plyometrics: skipping → hopping → jumping if symptom free • Sport specific exercises: agility drills, court drills • Outcome testing and assessment

- Specific exercises used in the training:
  - Continue with Phase I activities focusing predominantly on mobility and strength impairments.
  - Pool therapy: hopping and jumping beginning in chest deep water and progressing to waist-deep water
  - Gait training: Progress treadmill walking from flat surface to 2% to 5% incline. Use the Alter-G treadmill to progress the rate and duration of walking with body weight off-loading as needed for normal gait.
  - Submaximal isokinetic, concentric and light eccentric, DF and PF, focusing on endurance
  - Core training: lower extremity resistance (Figure 38-27), upper extremity resistance (Figure 38-28), or planks (front and side)
  - SL balance exercises: Progression from static stance with increasing levels of difficulty (i.e., transition from standing on firm surface to foam mat to ½ cylinder roller) to SL stance with dynamic movement initiated by the upper extremities or uninvolved lower extremity (Figure 38-29)
  - Balance and reach activities in the frontal, sagittal, and transverse planes with increasing training volume, amplitude, and rate of movement (Figure 38-30).
  - Bodyweight squats and lunges. Squats with varying base of support (Figure 38-31). Static lunges transitioning to dynamic multiplanar lunges (Figure 38-32).

FIGURE 38-28. Ball chest press. Core exercise with upper extremity resistance.

Application of Chronic Training Variables

Phase II includes an increase in aerobic training, early anaerobic training, and increasing focus on strength development. Training speed manipulations are also incorporated throughout the latter half of this phase.

- Cardiorespiratory training
  - Pool walking, progressing to jogging, in chest-high water
  - Stationary cycling using pre-programmed settings and mild to moderate resistance to enhance variability of training. Cycling duration may vary from 15 to 40 minutes. On training days with minimal strength training, cycling sessions may be of greater duration.
- Gait training
  - Treadmill walking progressing to lateral stepping, backward walking, ladder drills (i.e., shuffle steps, high knees) (Figure 38-33) at walking pace.
  - Schepsis et al. suggest that light jogging can begin at 3 months if the patient has regained full dorsiflexion.[7]

FIGURE 38-27. Lateral stepping with Thera-Band. Core exercise with lower extremity resistance.

FIGURE 38-29. Single leg stance with frontal plane well-leg movement.

FIGURE 38-31. A, Narrow based body weight squats. **B,** Wide stance or split stance body weight squats.

FIGURE 38-32. A, Static lunge. **B,** Dynamic lunge.

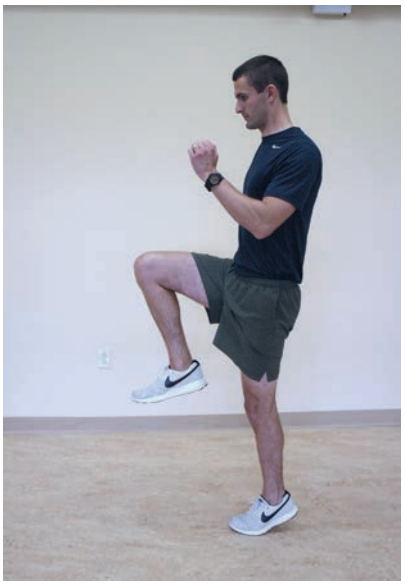

FIGURE 38-33. High knee walking.

Phase III: Sport-Specific Training

Periodization

- Mesocycle: weeks 17 to 36

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Training continuum
- Multiplanar training activities
- Training for optimum muscle functional strength
- Training for optimum muscle functional power
- Neuromuscular dynamic stability exercises
- Plyometric training
- Functional training

Olympic Lifts Used in the Training Program

- Snatch
- Power/hang clean

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload
- Principle of variation
- Principle of individualization
- Principles of specificity: specific adaptation to imposed demands (SAID)

Application of Acute Training Variables

- During this final rehabilitation stage the focus is on increasing speed of movement, normal amplitude of movements (symmetrical movement patterns to uninvolved limb).
- Force, load, number of sets, performance speed of the exercise, magnitude of movement during the exercise (ROM), type of contraction, and rest period.
- Exercises are predominantly integrated/complex and sport-specific movement patterns.
- Resistance exercises include a combination of concentric and eccentric loading.
- Repetitions of strength and power training are relatively low, with an increasing rest period to support neuromuscular recovery (work-to-rest ratio of 1:3 to 5).
- Essential to this final stage of rehabilitation is the integration of plyometric activities. The intensity for plyometrics varies depending on the activity and should start from relatively easy exercises, such as skipping, and progress to include higher-intensity exercises such as box jumps.
- The frequency of plyometric training should range from one to three sessions per week, allowing 48 to 72 hours of recovery between sessions.
- Rest between sets is generally 2 to 3 minutes, allowing a work-to-rest ratio of 1:5 to 1:10.
- Determination of training volume includes size of the athlete, prior plyometric training experience, and ultimately healing time for athletes recovering from injury.
- Training volume is determined by how many times the athlete's foot contacts the floor and the rehabilitation of an athlete may begin with 30 to 40 foot contacts.
- Athletic development training typically includes 80 to 140 contacts depending on the stage of training.[8]
- Repetitions: Plyometrics, 30 to 140 contacts per session. Lifts, three to six repetitions
- Sets: three to five
- Rest interval: work-to-rest ratio of 1:5 to 1:10 for plyometrics, 1:3 to 5 for lifts
- Intensity: moderate to high
- Training frequency: one to three times per week (no consecutive days)
- Training duration: 30 to 90 minutes
- Olympic lifts and strengthening: power/hang clean, jump squats, front squats, lunges, step-ups, calf raises (standing), eccentric gastroc-soleus (Figure 38-34)
- Phase I Plyometrics (weeks 2 to 4 of the final phase): two foot ankle hop, quick skipping, squat jump, jump over obstacle (forward and lateral)
- Phase II Plyometrics (weeks 4 to 10 of the final phase): Skip to power skip, alternate leg bounding (sagittal and frontal plane), single foot hops (i.e., line hops with side-to-side comparison, dot hops), and vertical jumps.
- Phase III Plyometrics (weeks 8 to 20 of the final phase): tuck jumps, countermovement jump, box drills (jump up/step down, step up/jump down), depth jump with vertical or lateral movement beginning with both legs and advancing to single leg
- Specific exercises used in training:
  - Progression of jogging to full weight bearing on basketball court. Jogging advances to involve increasing running speed, decreasing duration (i.e., line drills)
  - Sport-specific drills include lateral and diagonal agility drills, ladder drills, and inclusion of reactionary basketball court drills
  - Individualized strength and conditioning program focusing on individual impairments

FIGURE 38-34. A, Eccentric gastrocnemius biased loading. **B,** Eccentric soleus biased loading.

Application of Chronic Training Variables

- The final training phase focus is on anaerobic power, normalization of strength, speed, agility, quickness, flexibility, and power.
- This is the longest phase of recovery and requires attention to detail to ensure normalized movement patterns as the athlete begins sports. Enabling compensatory movement patterns is likely to delay full recovery and increase the risk of reinjury or creation of an injury elsewhere in the kinetic chain due to the compensation.
- Careful modification of these training variables is necessary to provide adequate overload without developing of symptoms of tendinopathy.
- Training sessions may include exercises distributed to address all the chronic factors or the training sessions may focus on one to two chronic factors (i.e., Monday—agility and quickness, Wednesday—strength and power).

Sports Performance Testing

General Information

- General history: training background, future occupational and sport demands/goals
- Subjective questionnaires: SF 12/36.
- Outcome surveys: Victorian Institute of Sport Assessment (VISA-A), Foot and Ankle Ability Measure (FAAM), Lower Extremity Functional Scale, Foot and Ankle Outcome Score, Achilles Tendon Total Rupture Score (ATRS)[5]
- Medical history: treatment in the past 12 months with fluoroquinolones
- Sports injury history: spine or other lower extremity injuries. Mechanism of injury. When injuries occurred (what part of season, what period of game or practice)
- Surgical history: spine or other lower extremity surgeries
- Chronic conditions/medications: soft tissue conditions, systemic disease

Objective Tests

- Physiological assessments
  - 20-meter sprint and suicide sprint beginning at 5 to 6 months with monthly reassessment
- Dynamic muscle performance testing
  - SL heel raise endurance assessing the number of repetitions beginning at 4 to 5 months with monthly reassessment
- Movement performance testing:
  - Ankle ROM to include closed kinetic chain assessment of DF beginning at 3 months and monthly thereafter
  - Functional Movement Screen: first assessment at approximately 3 months, and then every 4 to 6 weeks thereafter
- Sport-specific testing:
  - Single leg hop for distance at 5 to 6 months and monthly thereafter
  - SL vertical jump at 5 to 6 months and monthly thereafter
  - Triple hop for distance at 5 to 6 months and monthly thereafter
  - 6 meter timed SL hop at 5 to 6 months and monthly thereafter
  - Vertical jump test at 6 months and monthly thereafter
  - Agility T-test at 5 to 6 months and monthly thereafter
  - Drop counter movement jump at 6 months and monthly thereafter
- Others: isokinetic testing of ankle DF/PF and INV/EV if available

Specific Criteria for Progression to the Next Stage to Determine Readiness for Basketball

- Progression from one phase to the next is performance, not time, based.
- Progression to Phase II begins when the patient demonstrates ease with full weight-bearing ambulation, has closed kinetic chain dorsiflexion of 15°, and can do double leg heel raise without pain.
- Progression to Phase III begins when the patient displays a normal walking gait, able to descend stairs symmetrically, can squat and lunge with normal mechanics and absence of pain, is able to do 10 single leg heel raises, and is able to jog for a short duration without pain.

Specific Criteria for Release to Unsupervised Complete Participation in Basketball

- A minimum of 85% side-to-side symmetry is required on all testing before clearance for unrestricted sport.
- We recommend that testing be formed following a brief warm-up and again following a simulated, one-half basketball game at a moderate level of intensity.
- Following completion of the simulated game sport-specific testing and dynamic muscle performance testing should be reassessed to evaluate performance decrement on the involved side and comparison with the uninvolved lower extremity.

Recommended Ongoing Exercises

- Long-term training of muscles and movements should incorporate power lifts such as countermovement jumps, eccentric gastroc-soleus strengthening, triplanar SL hopping, and multi-planar dynamic lunges for successful sport performance and injury prevention.
- Additional sport specific training should include change of direction agility drills (i.e., line drills, T-drill).

Evidence

Alfredson H, et al: Heavy-load eccentric calf muscle training for the treatment of chronic Achilles tendinosis. *Am J Sports Med* 26:360–366, 1998.

This prospective study applied a heavy-load eccentric training program versus conventional treatment to 15 recreational athletes (in each group) with chronic Achilles tendinosis. Following the 12-week program all patients in the eccentric training group had returned to preinjury levels of activity. None of the patients in the conventional treatment group returned to preinjury activity levels. (Level II evidence)

DeLorme TL, Watkins AL: Technics of progressive resistive exercise. *J Bone Joint Surg* 27:163–173, 1945.

This landmark manuscript introduced the terms "progressive resistance exercise" and the "10 repetition maximum." The exercise program introduced in the this manuscript of three sets of 10 repetitions, with increasing amount of resistance, provides a systematic approach to muscular strengthening that is still used more than 65 years later. (Level V evidence)

Kannus P, et al: Etiology and pathophysiology of tendon ruptures in sports. *Scand J Med Sci Sports* 7:107–112, 1997.

This publication reviews the etiology and pathophysiology of Achilles tendon ruptures in sport related activity. The authors found that out of 430 cases of Achilles tendon rupture, 14% were suffered while playing basketball. It is also stated that 75% of all Achilles tendon ruptures are related to sport. (Level III evidence)

Mandelbaum B, et al: Achilles tendon ruptures: A new method of repair, early range of motion, and functional rehabilitation. *Amer J Sports Med* 23:392–396, 1995.

This prospective study treated 29 athletes with Achilles tendon ruptures according to a functional rehabilitation protocol. At 6 weeks 90% of patients had full ROM and 87% were able to perform a single-leg toe raise by 3 months postop. At 6 months 93% of patients had a full return to sport and 100% returned to sport by 12 months. (Level II evidence)

Nilsson-Helander K, et al: The Achilles Tendon Total Rupture Score (ATRS). *Am J Sports Med* 35:421–426, 2007.

This cohort study developed and validated a new patient report instrument for measuring outcome following Achilles tendon rupture. Multiple tests for statistical analysis concluded that the ATRS had high reliability, validity, and sensitivity outcome measurement in patients with a total Achilles tendon rupture. (Level I evidence)

Schepsis A, et al: Achilles Tendon Disorders in Athletes. *Am J Sports Med* 30:287–305, 2002.

This article reviews the anatomy and biomechanics of the Achilles tendon and the multiple different factors which can lead to injury. The authors suggest that Achilles tendon ruptures be treated through surgical intervention and rehabilitation focus on gradually increasing dorsiflexion through serial casting. At 3 months, if full dorsiflexion is gained, then the patient is permitted to perform light jogging. (Level V evidence)

Stanish WD, et al: Eccentric exercise in chronic tendinitis. *Clin Orthop Rel Res* 208;65–68, 1986.

This article proposes that eccentric loading is appropriate and necessary loading for optimal rehabilitation of chronic tendon injuries. The proposed eccentric training included various speed and amplitude of movement while producing minimal pain. (Level V evidence)

Multiple Choice Questions

QUESTION 1. Achilles tendon rupture secondary to athletic activity, specifically racquet or ball sports, has been noted in _____ of cases.

A. 50%
B. 65%
C. 75%
D. 95%

QUESTION 2. In the rehabilitation protocol for athletes who have suffered an Achilles tendon rupture, range of motion (ROM) exercise begins _____ postop.

A. 24 hours
B. 72 hours
C. 7 days
D. 2 weeks

QUESTION 3. When should low intensity jogging be initiated after an Achilles tendon rupture?

A. When sutures are removed
B. At 17 weeks if full plantar flexion strength is gained
C. When a single leg toe raise can be performed
D. At 3 months if full dorsiflexion is gained

QUESTION 4. When should gait training out of the splint begin following an Achilles tendon rupture in the athlete?

A. 5 weeks
B. 2 months
C. 10 weeks
D. 3 months

QUESTION 5. Which of the following is suggested as a sport-specific functional test for return to basketball following an Achilles tendon rupture?

A. Single leg toe raise
B. Counter movement jump
C. Pain free jogging
D. Skip to power skip

Answer Key

QUESTION 1. Correct answer: **C** (see Introduction)

QUESTION 2. Correct answer: **B** (see Introduction)

QUESTION 3. Correct answer: **D** (see Phase II)

QUESTION 4. Correct answer: **A** (see Phase I)

QUESTION 5. Correct answer: **B** (see Sports Performance Testing)

Chapter 39

Ankle Sprains, Fractures, and Chondral Injuries

INTRODUCTION

Annunziato Amendola, MD, Sebastiano Vasta, MD, and Biagio Zampogna, MD

Epidemiology

Age

- Under the age of 35 with a peak of incidence of 15 to 19 years of age.

Sex

- Slightly higher incidence of ankle sprain in males (1.04).

Sport

- Ankle sprains are the most common injury in all sports involving running and pivoting; basketball is the most common sport in the United States associated with ankle sprain but other include football, soccer, running, volleyball, softball, baseball, and gymnastics. Ice and water sports are less likely to cause an ankle sprain.

Position

- Among soccer players, defenders and attackers have a higher risk of ankle injury as a result of contact with opponents.

Pathophysiology

Intrinsic Factors

- Muscle strength imbalance: increased eversion-to-inversion ratio and plantarflexion-to-dorsiflexion
- Increased BMI
- Higher risk for dominant ankle in soccer
- History of previous ankle sprains
- Pes cavus or calcaneovarus alignment (Figure 39-1)

Extrinsic Factors

- Certain shoewear may predispose to ankle injury: air heels, poor fit
- Inadequate warmup with poor flexibility
- Artificial turf increases the risk of ankle injury

FIGURE 39-1 Assessing foot alignment: varus hindfoot alignment may predispose to recurrent ankle sprains.

Traumatic Factors

- Pronation-external rotation, pronation-abduction, and infrequently the supination external rotation mechanism are responsible for tibiofibular syndesmotic injuries and high fibular fractures.
- Supination and adduction (inversion) of the plantarflexed foot for lateral ligament injury and fibular avulsion fractures; same as a lateral ankle sprain.
- Rarely, eversion, external rotation, or abduction mechanism cause an isolated injury of the deltoid ligament, otherwise it is injured together with the other ligaments through the same pathway. Type B fracture (Weber classification) or Lauge-Hansen (supination-external rotation) could also be caused by these patterns of trauma.
- Osteochondral injuries occur most commonly in association with sprains and fractures. Direct axial loading with shear to the ankle with or without sprain could be responsible for osteochondral lesions, but is less common (Figure 39-2).

Classic Pathological Findings

- Ankle sprains are usually lateral and involve the anterior tibiofibular ligament (ATFL) 100% of the time (grade I), whereas the calcaneofibular ligament (CFL) is involved in 50% to 75% of more severe sprains (grade II and III).
- Syndesmosis sprains usually occur with external rotation and have a spectrum of severity: from a few fibers of the distal antero-inferior tibiofibular ligament (AITFL) (stable) to complete AITFL injury and interosseus membrane (unstable) with or without deltoid involvement (Figure 39-3*A-C*).
- OCLs occur in the medial (50%) and lateral (50%) talar dome: medial lesions are cup-shaped, usually posteromedial, and often related to chronic inversion trauma; lateral lesions are flat and anterolateral, usually following an acute sprain (Figure 39-4*A,B*).
- Ankle fractures have been classified by many authors. The most commonly used are the Denis-Weber and the Lauge-Hansen classifications. The Denis-Weber classification is based on the location of the fibular fracture. Lauge-Hansen classifies the fractures according to the foot position and the direction of the force determining the trauma.

FIGURE 39-2 Anterior-posterior view of the ankle following an ankle sprain: lateral osteochondral lesion flake shaped acute.

Clinical Presentation

History

- For an ankle sprain, patients usually describe an inversion-type twist of the foot and ankle, or less frequently, eversion, followed by pain and swelling.
- Swelling, ecchymosis, and tenderness laterally for lateral sprains and lateral malleolar fractures (Figure 39-5).
- Differentiate between ligamentous tenderness (ATFL, CFL, syndesmosis, deltoid) versus bony tenderness on examination.
- Decreased range of motion (ROM) with all injuries, more with fractures.
- Deformity may be present with displaced fractures.
- With sprains and osteochondral lesions (OCLs) it may be difficult to weight bear on the injured limb because of pain, but it is usually still possible to walk on the foot. Inability to weight bear on the injured foot usually indicates the presence of a fracture (Ottawa Ankle Rules).
- An osteochondral lesion or a loose body should be considered when persistent pain is present together with intermittent locking, stiffness, and limping (Figure 39-6).

Physical Examination

Abnormal Findings

- Knowledge of anatomy for palpation is essential. Pain and tenderness at the area of injury: ATFL and CFL in lateral sprains, bony tenderness and/or deformity and crepitus with fractures; AITFL, interosseus membrane and deltoid tenderness with syndesmosis injury.
- Positive anterior drawer test and talar tilt test in the setting of a lateral ankle injury; these are usually best in the subacute stage, a few days after injury.
- Positive squeeze test, external rotation stress test, cotton test, fibula translation test, and crossed-leg test for an acute syndesmotic injury. In the setting of a chronic injury, the stabilization test will be positive (Figure 39-7*A,B*).
- Osteochondral lesions usually determine tenderness in their common location site and joint line with the ankle in plantarflexion, anterolateral lesions will cause pain when palpating the anterolateral talar dome, whereas a posteromedial lesion will be tender behind the medial malleolus when palpating the posteromedial talus with the ankle in dorsiflexion.
- Possible deformity and\or skin laceration in the presence of a fracture.

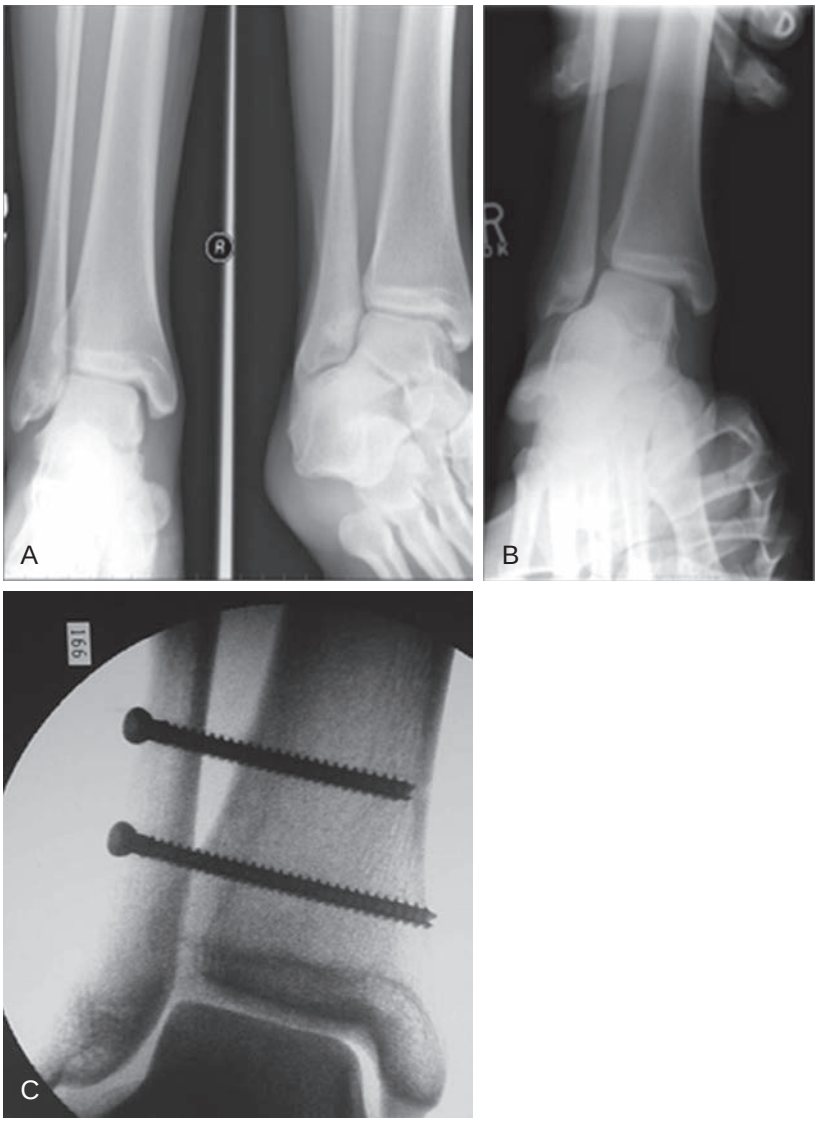

FIGURE 39-3 A, Anterior-posterior and mortise view: eversion external rotation ankle sprain, unable to weight bear. **B,** External rotation stress test; view confirms an unstable injury. **C,** Fixation of unstable syndesmosis (grade III) injury.

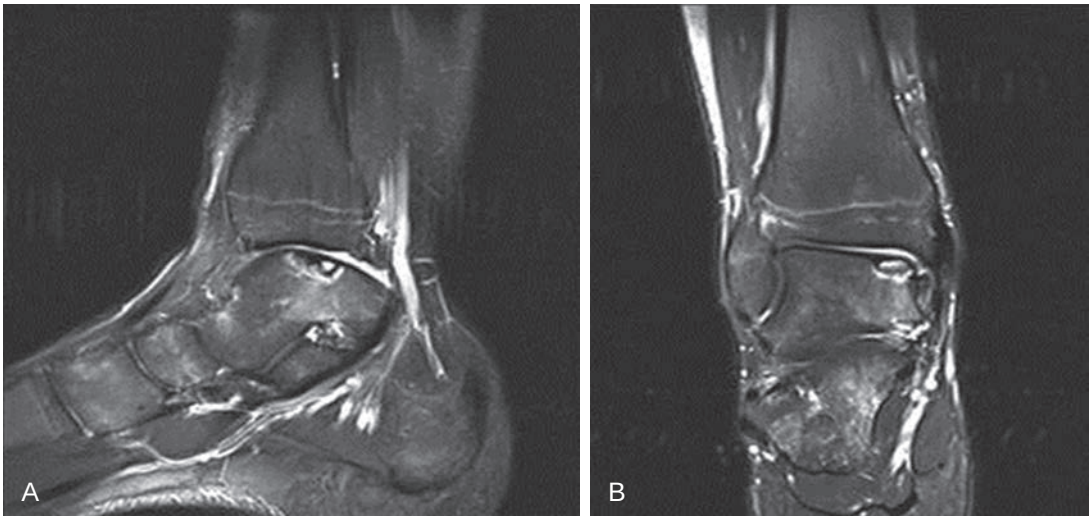

FIGURE 39-4 A, Magnetic resonance imaging (MRI) sagittal view: cup-shaped osteochondral lesion of the medial talar dome. **B,** MRI, Coronal view showing a cup-shaped osteochondral lesion of the talar dome.

FIGURE 39-5 Swelling and ecchymosis following a severe sprain of the left ankle.

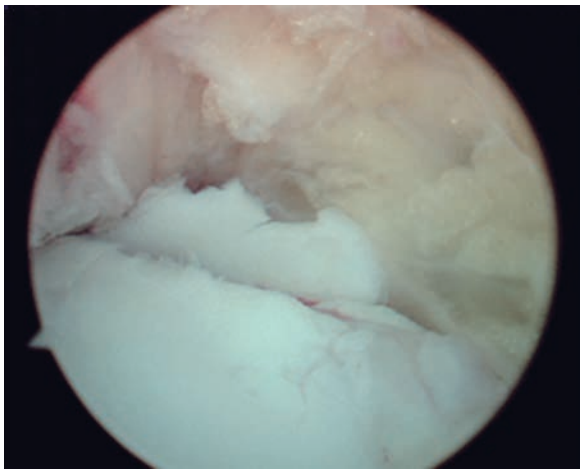

FIGURE 39-6 Arthroscopic view: chondral lesion following a severe ankle sprain.

Pertinent Normal Findings

- Normal neurovascular status
- In the setting of an ankle sprain, the patient should be able to walk even if painful. If not, a fracture should be investigated.

Imaging

- Routine plain radiographs with weightbearing anterior-posterior (AP), lateral, and mortise view to assess the presence of a concomitant fracture; the lateral view should include the base of the fifth metatarsal.
- External rotation stress views may be performed to assess the severity of syndesmotic or deltoid injury (Figure 39-3*B*).
- Magnetic resonance imaging (MRI) may be used to assess the extent of ligament injury (deltoid and syndesmosis) and the presence of nondisplaced fractures, bony edema from stress fractures, or osteochondral injury. It is indicated if the diagnosis is not clear, or if the athlete has persistent pain and loss of function (Figure 39-4*A*,*B*).
- Computed tomography (CT) scanning is useful to assess the extent of bone injury: intraarticular fractures, OCLs, or to evaluate bone healing in a fractured ankle.
- Triple-phase bone scintigraphy (bone scan) has been supplanted by MRI in the diagnosis of stress fracture, but may be useful for the investigation of diffuse bone or joint pain.

Differential Diagnosis

- Tendinopathy: peroneal tendons most commonly, tibialis posterior, flexor halluces longus (FHL) impingement, midportion and insertional achilles Achilles tendon ruptures.
- Stress fractures

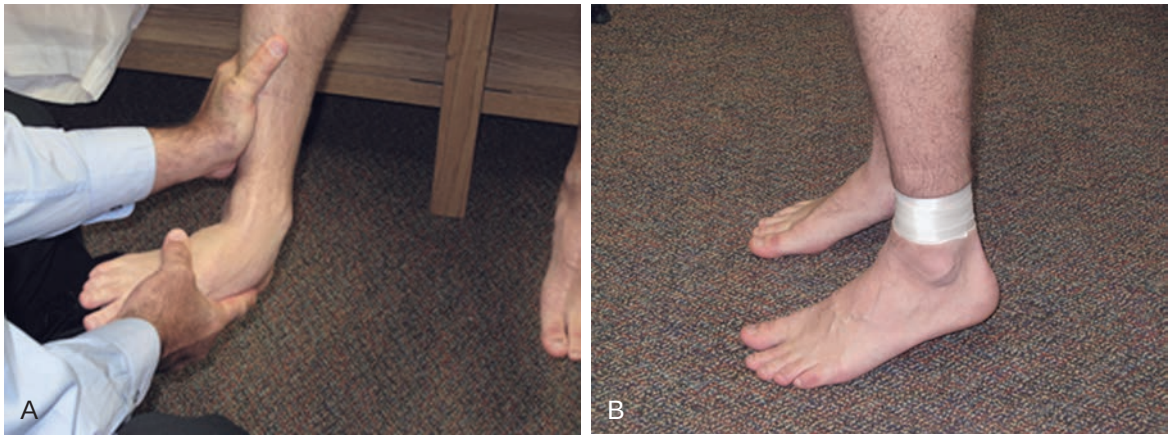

FIGURE 39-7 A, External rotation stress test. **B,** Stabilization test after taping technique just above the ankle joint; perform provocative activity to test syndesmotic stability.

Treatment

Nonoperative Management

- Lateral ankle and mild syndesmotic sprains are usually treated with rest, ice, compression, and elevation (RICE): nonsteroidal antiinflammatory drugs may be used for pain and swelling; a short period (1 to 2 weeks) of immobilization or comparable rigid support for grade I and II ankle sprains.
- Use of short leg cast or removable brace period for nondisplaced ankle fracture.
- Physical therapy aiming to regain ROM, strength, and proprioceptive function when appropriate for healing.

Guidelines for Choosing among Nonoperative Treatments

- All lateral ankle sprains, nonoperative treatment is preferred
- Grade I and grade II syndesmotic ligamentous injuries with a competent deltoid and posterior inferior tibiofibular ligament (PITFL) are generally treated using conservative measures.
- Stable and nondisplaced fractures
- Stable and nondisplaced osteochondral injuries
- In the setting of displaced osteochondral injuries, conservative measures are often unsuccessful, and surgical treatment (arthroscopy) may be more effective.

Surgical Indications

- Grade III injuries and fractures with syndesmotic instability (absolute indication)
- Weber A/supination-adduction (SA) 2 with associated vertical medial malleolar fracture
- Unstable Weber B/supination-external rotation (SER) 4 or Weber C/all pronation-external rotation (PER) 1–4 fractures
- Osteochondral lesion (relative indication)
- Failure of conservative measures resulting in chronic instability

Aspects of History, Demographics, or Exam Findings That Affect Choice of Treatment

- Stability of the injury pattern in fractures and syndesmotic injuries
- Level of competition and desire to return to sport
- Time point of the injury relatively to the season

Aspects of Clinical Decision Making When Surgery is Indicated

- Likelihood of success with nonoperative versus operative treatment
- Failure of rehabilitative programs
- Grade III injuries or fractures with syndesmotic instability
- Symptoms preventing ability to participate: i.e., complaints of ankle stiffness or catching with osteochondral injuries; recurrent sprains despite optimal rehabilitation
- Fracture displacement and joint instability/incongruity

Evidence

Baumhauer JF, Alosa DM, Renstrom AF, et al: A prospective study of ankle injury risk factors. *Am J Sports Med* 23:564–570, 1995.

This study examined the ankle injury risk factors on 145 college-aged athletes. The athletes were assessed before the athletic season and monitored throughout the season. (Level III evidence).

Beynnon BD, Renstrom PA, Alosa DM, et al: Ankle ligament injury risk factors: a prospective study of college athletes. *J Orthop Res* 19:213–220, 2001.

This is a prospective study on 118 Division I collegiate athletes who participated in soccer, lacrosse, or field hockey. The study furnishes interesting data about epidemiology and risk factors. (Level III evidence).

Choi GW, Choi WJ, Youn HK, et al: Osteochondral lesions of the talus: Are there any differences between osteochondral and chondral types? *Am J Sports Med* 41:504–510, 2013.

This is a retrospective study on 298 ankles that underwent arthroscopic marrow-stimulating procedures for OLTs. The purpose was to compare the clinical outcomes, demographics, and characteristics of osteochondral- and chondral-type lesions of OLTs. (Level III evidence).

Cloke DJ, Ansell P, Avery P, et al: Ankle injuries in football academies: a three-center prospective study. *Br J Sports Med* 45:702–708, 2011.

This well designed epidemiology study described the incidence of ankle injuries and studied the factors associated with increase of injury rate of young soccer players of three different Football Association (FA) academies. (Level III evidence).

Colvin AC, Walsh M, Koval KJ, et al: Return to sports following operatively treated ankle fractures. *Foot Ankle Int* 30:292–296, 2009.

This study investigated which variables influence patients' return to sports after operative fixation of an unstable ankle fracture from 243 patients that were identified as participating in vigorous activity. (Level IV evidence).

Kaminski TW, Hertel J, Amendola N, et al: National Athletic Trainers' Association position statement: conservative management and prevention of ankle sprains in athletes. *J Athl Train* 48:528–545, 2013.

This is a recent position statement of the NATA. The recommendations for athletic trainers and other allied healthcare professionals in the conservative management and prevention of ankle sprains in athletes are presented. (Level IV evidence).

Kerkhoffs GM, van den Bekerom M, Elders LA, et al: Diagnosis, treatment and prevention of ankle sprains: an evidence-based clinical guideline. *Br J Sports Med* 46:854–860, 2012.

This work furnishes recommendations for diagnosis, treatment, and prevention of ankle sprain based on evidence from published scientific research. (Level II evidence).

Lauge-Hansen N: Fractures of the ankle: II: combined experimental-surgical and experimental-roentgenologic investigations. *Arch Surg* 60:957–985, 1950.

This is the original paper of Lauge-Hansen describing his classification of ankle fractures. (Level IV evidence).

Mintz DN, Tashjian GS, Connell DA, et al: Osteochondral lesions of the talus: a new magnetic resonance grading system with arthroscopic correlation. *Arthroscopy* 19:353–359, 2003.

This study, by using arthroscopy as the standard, demonstrated that magnetic resonance imaging can be used to evaluate the articular cartilage covering osteochondral lesions of the talus with a high degree of accuracy. (Level II evidence).

Rolf CG, Barclay C, Riyami M, et al: The importance of early arthroscopy in athletes with painful cartilage lesions of the ankle: a prospective study of 61 consecutive cases. *J Orthop Surg* 1:4, 2006.

This is a prospective study on 61 consecutive athletes over a 4-year period. The authors evaluated clinical presentation and outcomes of surgery for symptomatic chondral injuries of the talocrural joint in athletes. Secondly, in applicable cases, they evaluated the accuracy of MRI in detecting these injuries.

They found that arthroscopy should be taken into account as an early diagnostic and therapeutic tool in athletes complaining of exertion ankle pain. (Level IV evidence).

Sanders DW, Tieszer C, Corbett B, Canadian Orthopedic Trauma Society: Operative versus nonoperative treatment of unstable lateral malleolar fractures: a randomized multicenter trial. *J Orthop Trauma* 26:129–134, 2012.

This randomized multicenter clinical trial compared functional outcomes after operative and nonoperative treatment of undisplaced, unstable, isolated fibula fractures without any differences between the two groups, but with a higher risk of displacement and problems with union in the nonoperative managed group. (Level I evidence).

Stiell IG, Greenberg GH, McKnight RD, et al: Decision rules for the use of radiography in acute ankle injuries. Refinement and prospective validation. *JAMA* 269:1127–1132, 1993.

This study was conducted to validate the Ottawa Rules that aid the efficient use of radiography in acute ankle injuries. (Level I evidence).

Stufkens SA, Knupp M, Horisberger M, et al: Cartilage lesions and the development of osteoarthritis after internal fixation of ankle fractures: a prospective study. *J Bone Joint Surg Am* 92:279–286, 2010.

The aim of this study was to assess the role of the location and severity of initial cartilage lesions associated with an ankle fracture in the development of posttraumatic osteoarthritis. The authors found that the initial cartilage damage seen arthroscopically following an ankle fracture is an independent predictor of the development of posttraumatic osteoarthritis. (Level IV evidence).

van Dijk CN, Lim LS, Bossuyt PM, et al: Physical examination is sufficient for the diagnosis of sprained ankles. *J Bone Joint Surg Br* 78:958–962, 1996.

This study aimed to assess the diagnostic accuracy of physical examination to diagnose ankle sprain. It demonstrated that delayed physical examination gives information of diagnostic quality which is equal to that of arthrography, and causes little discomfort to the patient. (Level II evidence).

Weber BG: *Die verletzungen des oberen sprunggelenkes*, ed 2, Berne, 1972, Verlag Hans Huber.

This is the original paper in which Weber describes his classification of the ankle fracture based on the one proposed by Denis in 1949. (Level IV evidence).

Zengerink M, Struijs PA, Tol JL, et al: Treatment of osteochondral lesions of the talus: a systematic review. *Knee Surg Sports Traumatol Arthrosc* 18:238–246, 2010.

This is a systematic review of studies comparing the effectiveness of treatment strategies for osteochondral defects (OCD) of the talus. The authors concluded that debridement and bone marrow stimulation is the most effective treatment strategy for symptomatic osteochondral lesions of the talus.

Multiple-Choice Questions

QUESTION 1. Which of the factors below increase the risk for ankle sprain?

A. High-top shoes
B. Pes planus
C. Previous history of ankle sprain
D. Shoes with a heel counter
E. None of the above

QUESTION 2. A 20-year-old male basketball player suffered an inversion ankle sprain 4 weeks ago. He continues to have ankle pain and swelling despite optimal physical therapy. X-rays were normal. What would be the next step in management?

A. Nonsteroidal antiinflammatory drugs (NSAIDs) medication
B. Corticosteroid injection
C. Immobilize in a boot for 4 weeks
D. Magnetic resonance imaging (MRI) of the ankle
E. Arthroscopic surgery

QUESTION 3. Among the following findings, which one is strongly suggestive for an ankle fracture ?

A. Pain
B. Swelling
C. Inability to bear any weight on the injured foot
D. Hematoma
E. Decreased ankle range of motion

QUESTION 4. Which are the most important parameters that guide the type of treatment in an ankle fracture?

A. Mechanism of trauma
B. Type of sport activity level
C. Displacement and stability of the joint
D. Type of fracture

Answer Key

QUESTION 1. Correct answer: **C** (see Pathophysiology)

QUESTION 2. Correct answer: **D** (see Clinical Presentation)

QUESTION 3. Correct answer: **C** (see Clinical Presentation)

QUESTION 4. Correct answer: **C** (see Treatment)

NONOPERATIVE REHABILITATION OF LATERAL AND SYNDESMOTIC SPRAINS

Paul J. Pursley, PT, SCS, CSCS, and Annunziato Amendola, MD

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- Protection of injured structures/prevent reinjury
- Reduction of effusion/edema/pain control/regain normal joint motion
- Normalization of gait/joint control
- Return to preinjury activity levels

Phase I (week 0 to 1)

Protection

- Protected weightbearing with crutches (see Box 39-1: Ottawa Rules), immobilization boot for pain control.

Management of Pain and Swelling

- PRICE principles: Protection, Rest, Ice, Compression, Elevation
  - See Figure 39-8: Lateral sprain
  - See Figure 39-9: Syndesmotic sprain

BOX 39-1 Ottawa Rules Classification

X-rays are only required if there is pain in the malleolar zone and if there is:

- bone tenderness along the distal 6 cm of the posterior edge of the tibia or tip of the medial malleolus, OR
- bone tenderness along the distal 6 cm of the posterior edge of the fibula or tip of the lateral malleolus, OR
- an inability to bear weight both immediately, and in the emergency department for four steps

FIGURE 39-8 Day 2 status post (s/p) lateral ankle sprain.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Anterior to posterior fibular mobilization (lateral sprains)

Soft Tissue Techniques

- Distal to proximal soft tissue mobilization/edema massage

Stretching and Flexibility Techniques for the Musculotendinous Unit

- OKC ankle motion for all planes
- Nonweightbearing dorsiflexion stretch with UE assist, for syndesmotic sprains, axial traction to hindfoot during stretch to improve comfort.

TIMELINE 39-1: **Conservative Care Following Lateral or Syndesmotic Sprain**

PHASE I (days 0 to 5)	PHASE II (days 6 to 12)
• Protected weightbearing-crutches/immobilization boot • Ice/compression/elevation • Nonweightbearing AAROM for eversion/dorsiflexion/plantarflexion • Seated BAPS board proprioceptive training • Isometric strengthening in midrange • Stationary biking	• Progressive weightbearing as tolerated • Icing as needed for edema/pain control • Soft brace/taping for stability • OKC AROM for all planes • Anterior to posterior talocrural joint mobilization • Isotonic strengthening with band resistance • Standing bilateral heel raises • Progressive weightbearing BAPS training • Bilateral unstable surface stance (sport-specific perturbations as tolerated) • Machine-based leg strengthening • Elliptical trainer • Progressive walking speeds on levels

FIGURE 39-9 Day 2 s/p lateral and syndesmotic sprain. Note: ecchymosis more proximal and anterior.

Other Therapeutic Exercises

- TBS, core stability, contralateral TLS
- Initiate isometrics progressing to isotonics with elastic band resist for inversion/eversion/DF/PF as tolerated by pain.

Activation of Primary Muscles Involved

- Peroneus longus/brevis (lateral and syndesmotic)
- Tibialis anterior (syndesmotic)
- FHL/tibialis posterior/EHL
- Gastrosoleus

Sensorimotor Exercises

- Intrinsic foot motion (toe extension with ankle PF/toe flexion with ankle DF)
- Seated circle board progressing to bilateral limb stance balance progression (as tolerated by pain, generally will be initiated earlier for lateral vs. syndesmotic)

Open and Closed Kinetic Chain Exercises

- Isometric ankle inversion/eversion
- Band-resisted inversion/eversion/PF/DF
- Manual-resisted ankle motions with variable speed/pressure
- CKC wall sits, partial squats
- OKC ipsilateral hip/knee exercise

Techniques to Increase Muscle Strength, Power, and Endurance

- Biking
- Swimming with limited kicking
- Pool exercises in the deep end to limit weightbearing; focus on hip knee and ankle active ROM

Neuromuscular Dynamic Stability Exercises

- Static hold to manual perturbation in open kinetic chain
- Seated BAPS/circle board

Functional Exercises

- Functional stepping as tolerated by pain

Milestones for Progression to the Next Phase

- Symmetrical and pain-free gait at self-selected pace on even surfaces
- Full AROM, minimal pain with passive overpressure
  - Dorsiflexion/eversion (syndesmotic)
  - Plantarflexion/inversion (lateral)
- Full and symmetrical unilateral heel raise

Phase II (Lateral sprains: weeks 1 to 3; Syndesmotic sprains: weeks 2 to 4)

Protection

- Protective bracing (lace up or Velcro strapping)

Management of Pain and Swelling

- Continued compression and icing/cooling as needed

TIMELINE 39-1: **Conservative Care Following Lateral or Syndesmotic Sprain** (Continued)

PHASE III (days 13 to 21)	PHASE IV (weeks 3 to 6)
• CKC gastroc/soleus stretching • CKC heel raises in single limb stance • Bilateral to unilateral stance progression (stable-unstable) • Jogging as tolerated • Progressive speed lateral shuffling • Ladder drills A/P/lateral • Bilateral hopping	• Progressive speed running • Lateral change of direction drills • Unilateral directional hopping • Sport-specific reaction drills • Practice-based drills • Return to sport as tolerated • Continue proprioceptive exercise for injury prevention

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Anterior to posterior talocrural mobilization to improve dorsiflexion

Soft Tissue Techniques

- Distal to proximal soft tissue mobilization/edema massage; advance tissue mobilization depth as needed.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Standing gastroc-soleus (G-s) stretching for lateral sprains
- Manual G-s stretching while maintaining traction on the ankle joint to prevent impingement pain with syndesmotic sprains.

Other Therapeutic Exercises

- Isotonics for involved ankle (band, cords, manual resistance by ATC/PT
- Bilateral standing toe raises through full range (angle board, stairs)
- Nonimpact TLS for involved side
  - Leg press, machine based hips/quads/hamstrings

Activation of Primary Muscles Involved

- Peroneus longus/brevis (lateral and syndesmotic)
- Tibialis anterior (syndesmotic)
- FHL/tibialis posterior/EHL
- Gastrosoleus

Sensorimotor Exercises

- Progression for bilateral to unilateral stance with sport-specific perturbation (chest pass/overhead pass, volleyball passing, hand fighting for football/wrestling)
- Bilateral stance on unstable surfaces, adding modifications such as active ankle motion, squats, or perturbations as tolerated
- Light intensity ladder drills, starting with A/P motion, progressing to diagonals and laterals and tolerated by pain and movement patterns
- Star Excursion Balance Test (SEBT). Initiate with posterior reaching to reduce pain associated with dorsiflexion.

Open and Closed Kinetic Chain Exercises

- Progress OKC isotonics w/band or manual resist
- CKC squats, lunges, lateral lunges, step-ups

Techniques to Increase Muscle Strength, Power, and Endurance

- Elliptical
- Walk to jog on treadmill or level surfaces
- Lateral slide board
- Swimming with full kicking
- Pool-based running

Neuromuscular Dynamic Stability Exercises

- Static hold to manual perturbation in closed kinetic chain

Plyometrics

- Bilateral partial anterior jumping
- Pool-based jumping bilateral to unilateral as tolerated by pain

Functional Exercises

- Step-ups/step-downs with free weight resistance

Sport-Specific Exercises

- Ball-based activity (passing/catching/fielding)
- Ground-based stick work (field and ice hockey)

Milestones for Progression to the Next Phase

- Minimal to no effusion/edema
- Symmetrical running gait
- No reports of pain or instability with bilateral anterior hopping
- Full, pain-free AROM. Full PROM with minimal pain (<2/10 per VAS)

Phase III (Lateral sprains: weeks 3 to 6; Syndesmotic sprains: weeks 4 to 6)

Protection

- Soft bracing as needed for stability and injury prevention

Management of Pain and Swelling

- Icing as needed

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Continued AP talocrural mobilization for dorsiflexion

Soft Tissue Techniques

- Deep soft tissue mobilization at peroneus longus/brevis as needed for tissue release

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Generalized ankle stretching in closed chain

Other Therapeutic Exercises

- Return to previous global strengthening program
- Modify foot position as needed per reports of pain for dynamic lifts where involved leg is trail leg. This will be most problematic for syndesmotic sprains (split position).

Sensorimotor Exercises

- Unilateral stance on unstable surfaces (See Figure 39-10*A*,*B*)
- Unilateral stance with perturbation on stable/unstable surfaces
- Full speed planned movement drills
  - Ladder drills
  - Cone drills
- Unilateral jumps to unstable surfaces (foam pad/BOSU)

Open and Closed Kinetic Chain Exercises

- Weighted squats/lunges/lateral lunges/step-ups
- Olympic lifts with cuing for good technique
- Standing-resisted hip movement without UE assist

Techniques to Increase Muscle Strength, Power, and Endurance

- Treadmill running levels and inclines
- Sport cord resisted sprint intervals anterior/posterior/lateral
- Cord resisted lateral slide board
- Cord resisted skate sprints (as applicable per sport and facilities)

Plyometrics

- Box jumps
- Bounding
- Hurdle drills bilateral to unilateral
- Split jumps
- Directional jumping
  - Planned
  - Reaction based on command

Sport-Specific Exercises

- Sport-specific multidirectional movement progressing from planned to reactive drills

Milestones for Progression to the Next Phase

- Symmetrical and pain-free sprints
- Unilateral hopping <90% of contralateral LE
- Full passive range without pain
- SEBT <95% contralateral LE

Phase IV (weeks 6 to 18)

Protection

- Prophylactic soft bracing

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Stretch program/ maintenance

Other Therapeutic Exercises

- Maintain global strengthening program

Activation of Primary Muscles Involved

- Peroneus longus/brevis (lateral and syndesmotic)
- Tibialis anterior (syndesmotic)

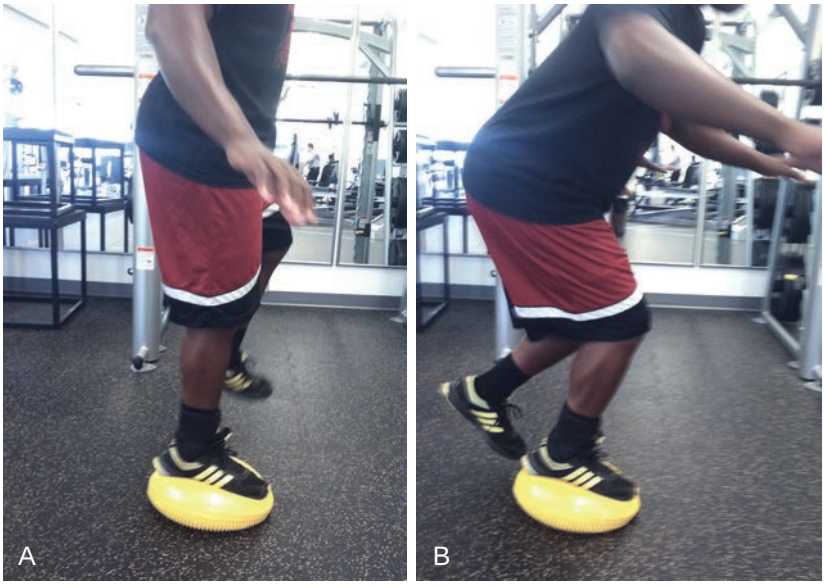

FIGURE 39-10 Single limb stance on disk for proprioception with progression of dorsiflexion and sport-specific positioning. Upright position (**A**); flexed position (**B**).

- FHL/tibialis posterior/EHL
- Gastrosoleus

Sensorimotor Exercises

- Unilateral balance activities for injury prevention

Sport-Specific Exercises

- Return to full competitive sport/ prophylactic soft bracing or taping

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- Able to function maximally for activity
- No swelling, little or no pain with activity, able to perform near previous levels

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention

- Instability during sport-based activity
- Giving way episodes consistent with inversion instability for lateral ankle sprains; continuing pain with dorsiflexion and external rotation loading of the ankle
- Intractable pain due to impingement or instability or osteochondral injury
- Limited ROM due to scarring or impingement.

Tips and Guidelines for Transitioning to Performance Enhancement

- Be cautious with transition to resisted or plyometric exercise as the involved LE is the trail leg. The foot/ankle complex will be forced into dorsiflexion, which can be more painful, especially following a syndesmotic sprain.
- No exercise should be advanced or progressed until the exercise can be performed with good technique.
- With high demand activity and sport-specific exercises, prophylactic bracing is recommended

Performance Enhancement and Beyond Rehabilitation: Training/Trainer and Optimization of Athletic Performance

- Ankle sprains, both high and low (lateral) predispose athletes to recurrent injury.
- Prophylactic maintenance of balance, neuromuscular control, strength and flexibility is important to minimize re-injury
- Prophylactic bracing is recommended

Specific Criteria for Return to Sports Participation: Tests and Measurements

- No reported instability while braced during high level practice situations
- Symmetrical gait for maximum speed sprints and shuffles
- Unilateral hopping/jumping < 90% of contralateral side

Evidence

Bleakley CM, O'Connor SR, Tully MA, et al: Effect of accelerated rehabilitation on function after ankle sprain: randomised controlled trial. *BMJ* 10(340):c1964, 2010.

A blinded, randomized controlled trial of 101 patients sustaining grade I or II lateral ankle sprain. The accelerated exercise group demonstrated improved function during the first 2 weeks following injury.

Hubbard T, Denegan C: Does cryotherapy improve outcomes with soft tissue injury? *J Athl Train* 39:278–279, 2004.

Specific search criteria identified 55 articles for review, of which 22 were eligible randomized, controlled clinical trials. Based on the available evidence, cryotherapy seems to be effective in decreasing pain. High-quality studies are required to create evidence based guidelines on the use of cryotherapy. These must focus on developing modes, durations, and frequencies of ice application that will optimize outcomes after injury.

Hupperets MD, Verhagen EA, van Mechelen W: Effect of unsupervised home-based proprioceptive training on recurrences of ankle sprain: Randomised controlled trial. *BMJ* 339:b2684, 2009.

Randomized controlled trial studying the effects of a home-based proprioceptive program to reduce the recurrence of ankle sprains over a one-year time frame; 522 athletes randomized into intervention and control groups; 22% of intervention group.

Konradsen L, Olesen S, Hansen HM: Ankle sensorimotor control and eversion strength after acute ankle inversion injuries. *Am J Sports Med* 26:72–77, 1998.

Forty-four subjects immediately postlateral ankle sprain were tested and retested with regard to maximal eversion strength and joint position sense at weeks 1, 3, 6, 12 after acute injury. Joint position sense can be affected up to 12 weeks post injury. Isometric eversion strength was significantly decreased at 3 weeks after injury, but had returned to normal values at 6 weeks after injury.

Nyanzi CS, Langridge J, Heyworth JR, et al: Randomized controlled study of ultrasound therapy in the management of acute lateral ligament sprains of the ankle joint. *Clin Rehabil* 13:16–22, 1999.

Randomized controlled trial of 51 patients receiving either placebo or active ultrasound following acute ankle sprain. No differences noted between groups, however, both groups improved in pain control and edema within the variable of time.

Thacker SB, Stroup DF, Branche CM, et al: The prevention of ankle sprains in sports. A systematic review of the literature. *Am J Sports Med* 27:753–760, 1999.

This systematic review identified 113 studies reporting the risk of ankle sprains in sports, methods to provide support, the effect of these interventions on performance, and comparison of prevention efforts. The most common risk factor for ankle sprain in sports is history of a previous sprain. Based on the review, it was recommended that athletes with a sprained ankle complete supervised rehabilitation before returning to practice or competition, and those athletes suffering a moderate or severe sprain should wear an appropriate orthosis for at least 6 months.

Van Rijn RM, van Os AG, Bernsen RM, et al: What is the clinical course of acute ankle sprains? A systematic literature review. *Am J Med* 121:324–331, 2008.

This review presents the clinical course of pain, objective and subjective instability, and subjective recovery of adult patients with conventionally treated ankle sprains. In total, 31 studies were included, from which 24 studies were of high quality. A risk factor for residual symptoms might be sports activity at a high level, but more studies evaluating prognostic factors in patients with acute ankle sprains are needed.

Verhagen E, van Mechelen W, de Vente W: The effect of preventive measures on the incidence of ankle sprains. *Clin J Sports Med* 10:291–296, 2000.

A systematic review from 1980 to 1998 with eight studies meeting the criteria. The review suggested evidence for taping and prophylatic bracing to reduce incidence and severity of ankle sprains. There was also evidence that preventative measures are as effective at reducing ankle sprain in both athletes with and without a history of recurrent sprain.

Wikstrom EA, Naik S, Lodha N, et al: Balance capabilities after lateral ankle trauma and intervention: a meta-analysis. *Med Sci Sports Exerc* 41:1287–1295, 2009.

A total of 37 articles were included in a meta-analysis of postural sway following acute and chronic lateral ankle sprain. Postural control impairments are present in patients with both a short and a long history of lateral ankle sprains. Balance/coordination training programs improve the postural control scores of patients with an acute lateral ankle sprain and with CAI. Further research needs to determine the optimal dosage, intensity, and type of training needed to maximize postural control improvements and to reduce recurrent ankle injuries. Further research also needs to evaluate a risk reduction/preventative effect associated with balance training after both acute and chronic ankle trauma.

Multiple-Choice Questions

QUESTION 1. Which of the following is important in preventing a recurrent ankle sprain?

A. Prophylactic bracing
B. Decreased range of motion
C. Hop test less than 50% the opposite side
D. Presence of joint swelling

QUESTION 2. Which of the following indicates that it is safe to return to sport?

A. Pain during jumping activity
B. No pain or swelling of the ankle after a heavy workout with sport-specific exercises
C. Daily antiinflammatory medication is still required for pain control after sport-specific exercises
D. A mild limp with sport-specific exercises

QUESTION 3. Which of the following is the most significant difference between a high ankle sprain and a lateral ankle sprain?

A. Rehab protocol
B. Likelihood of recurrent injury
C. Expected time to return to sport
D. Likelihood of surgery

QUESTION 4. Which of the following modalities is not recommended following an ankle sprain?

A. Immobilization
B. Heat therapy
C. Cold therapy
D. Antiinflammatory medication

QUESTION 5. Which of the following is an indication for surgical management of a lateral ankle sprain?

A. Pain at 3 weeks following the sprain
B. Decreased ROM at 3 weeks following a sprain
C. Recurrent ankle sprains after optimal rehabilitation
D. Presence of a small avulsion fracture off the distal fibula

Answer Key

QUESTION 1. Correct answer: **A** (see Protection)

QUESTION 2. Correct answer: **B** (see Milestones for Progression to Advanced Sport-Specific Training and Conditioning)

QUESTION 3. Correct answer: **C**

QUESTION 4. Correct answer: **B**

QUESTION 5. Correct answer: **C** (see Criteria For Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention)

POSTOPERATIVE REHABILITATION AFTER LATERAL ANKLE LIGAMENT REPAIR/RECONSTRUCTION

Scot A. Youngblood, MD, CDR, MC, USN, and William E. Burns, Jr., DPT, OCS, SCS

Indications for Surgical Treatment

- Recurrent lateral ankle instability despite an appropriate course of nonoperative care: rehabilitative exercises and ankle supportive (lace-up) bracing.

Brief Summary of Surgical Treatment

Major Surgical Steps

- Examination under anesthesia—anterior drawer and talar tilt testing for confirmation of excessive laxity
- Open surgical approach to anterior talofibular ligament (ATFL) and calcaneofibular ligament (CFL)
- Inspection of peroneal tendons as appropriate
- Shortening and repair of native tissue to anatomic attachment points on the fibula of both the ATFL and CFL
- Imbrication of the repair with the inferior extensor retinaculum (Gould modification)

Factors That May Affect Rehabilitation

Anesthetic

- For the vast majority of cases, rehabilitation is delayed until at least the 2-week mark. Barring any anesthetic complication, there should by this time be no persistent impact of the choice of anesthetic at the first rehabilitation session.

Surgical

- Arthroscopy of ankle: Some experts recommend a routine diagnostic arthroscopy of the ankle before the ligament repair. Intraarticular lesions encountered are treated as appropriate: osteochondral lesion of the talus microfracture, synovectomy, or postinjury scar debridement.
- Tissue augmentation: In the setting of atrophic native tissues, the surgeon may opt to perform a reconstruction with tendon autograft or allograft (most commonly a gracilis or semitendinosus hamstring tendon). Most experts recommend a slower progression of activities after implantation of grafted tissue, especially allograft (donated tissue).
- Peroneal tendon repair or tenodesis: Peroneal tendinopathy (tendinitis and tears) can occur with inversion injuries to the ankle. Chronic pain or swelling in the area of the tendons and preoperative imaging may demand exploration of the tendons at the time of the surgery. Indicated treatment can include a tenosynovectomy, tendon repair, or tenodesis (removal of the diseased tendon and suturing of the remaining tendon ends to the other peroneal tendon).
- Hindfoot or forefoot realignment: Some patients with ankle instability have a predisposing architecture to their foot: cavovarus (inverted heel and a high arch). Realignment osteotomies of the heel and/or the forefoot may be indicated to protect the repair and prevent additional inversion injuries. Typically these osteotomies are kept nonweightbearing for 6 weeks before progression of weightbearing.

Other Surgical Techniques and Options

- It has been said that many foot and ankle surgeons perform a "Brostrom", but every one of them performs it slightly differently. Choices available to the operative surgeon beyond those listed in the section above include repairing only the anterior talofibular ligament (and not the calcaneofibular ligament), performing a midsubstance repair versus reattaching the ligaments to bone, using suture anchors versus drill holes in the bone to accomplish the repair, choosing not to incorporate the inferior extensor retinaculum, sacrificing a portion of a peroneal tendon in order to reinforce the repair, and choice of suture (absorbable suture versus second generation high tensile strength polyethylene braided suture). These multiple variables underscore the importance of communicating with the operative surgeon regarding the planned rehabilitation protocol to ensure it is neither too aggressive nor too restrictive for the specific repair that was performed.

Before Surgery: Overview of Goals, Milestones, and Guidelines[1]

- Resolution of any residual swelling in the involved ankle
- Restoration of full active range of motion in all directions
- Normalize gait pattern
- Maximize static and dynamic single-limb standing balance in the involved ankle
- Maximize strength of the peroneals, gastrocnemius/soleus complex, and tibialis anterior and posterior muscles

[1]*Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

GUIDING PRINCIPLES OF POSTOPERATATIVE

- Understand the anatomical basis of the surgical repair performed
- Understand any additional procedures performed and their implications for the patient's specific postoperative rehabilitation
- Know the positions and activities that will stress the repaired structures, and avoid these until the appropriate timeframe
- Progressive advancement of activities with adequate protection of healing structures

Phase I: Immediate Postoperative Period (days 0 to 14)

Clinical Pearls

- Patients should be encouraged to keep their operative extremity elevated in their nonweightbearing splint, especially for the first 3 to 5 days after their surgery, during which swelling peaks.
- No study has shown an advantage to motion before the 2-week point, at which skin sutures are often removed. The desire to aggressively begin therapy in the anxious patient must be balanced by the potentially significant complications of wound dehiscence and infection. Most patients have healed their incisions adequately by 2 weeks to have their sutures removed, Steri-Strips applied, and gently begin progressive range of motion.

Goals

- Allow adequate resolution of swelling and pain with appropriate soft tissue rest after the surgical procedure.
- Allow the incision to heal adequately before the institution of motion and aggressive advancement of range of motion exercises.
- Preserve full range of motion of the ipsilateral hip, knee, and digits.

Protection

- Nonweightbearing in a posterior splint secured with elastic bandage.
- Crutch ambulation

Management of Pain and Swelling

- Oral analgesic medication and ice
- Rest, ice, compression, and elevation
- Commercially available sequential compression cryotherapy devices may be used to control and reduce swelling

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Active range of motion activities for the ipsilateral hip, knee, and digits during the protection phase

Other Therapeutic Exercises

- Upper body ergometry to maintain cardiovascular fitness

Milestones for Progression to the Next Phase

- Healing of the surgical incision with reduction of postoperative swelling.

Phase II (weeks 2 to 6)

Clinical Pearls

- Ensure normal mobility of the surgical incision and underlying tissues in order to prevent the development of adhesions that could impede the progression of range of motion.
- Neuromuscular electrical stimulation (NMES) can be used to facilitate activation of the peroneus longus and brevis as well as the tibialis anterior muscles in cases of inhibition.
- If available and when the surgical incision is fully healed, aquatic therapy, particularly water walking, can help facilitate lower extremity strengthening and the return to a normal walking pattern.
- Articulated Cam Walker Range of Motion Progression. Another option for rehabilitation in this timeframe is to utilize an articulated cam walker with adjustable range of motion stops to allow protected early motion. During the third and fourth weeks postoperatively, 10° of dorsiflexion and 20° of plantarflexion are allowed while the patient is weightbearing as tolerated. During the fifth and sixth weeks, 20° of dorsiflexion and 40° of plantarflexion are allowed. (See Evidence References, Karlsson et al.) Obviously this rehabilitative option would be dependent on the availability of an articulated cam walker and would be in addition to the therapy discussed in this section.

Goals

- Resolution of postoperative swelling
- Transition to Weight Bearing As Tolerated (WBAT) in cam walker
- Increase dorsiflexion in the operative ankle to at least 10°
- Increase plantarflexion in the operative ankle to at least 30°
- Increase strength in the peroneals, gastrocnemius/soleus complex and tibialis anterior and posterior muscles to at least 3+/5

Protection

- WBAT with the use of a cam walker
- A standard cam walker can be used or, if available, an articulated cam walker may be employed to allow for the progression of functional yet protected range of motion in the talocrural joint (see Clinical Pearls).

Management of Pain and Swelling

- Acetaminophen and/or NSAIDs as needed
- Ice and elevation following physical therapy and other periods of prolonged standing and/or walking
- Commercially available sequential compression cryotherapy devices may be used to control and reduce swelling

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

Tarsometatarsal and intermetatarsal joint mobilization in the operative foot

Soft Tissue Techniques

- Scar mobilization and retrograde massage to prevent adhesions at the surgical site and mobilize edema

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Active-assisted range of motion of the talocrural joint to 10° of dorsiflexion and 30° of plantarflexion

Other Therapeutic Exercises

- Upper body ergometry to maintain cardiovascular fitness
- Upper body strengthening activities as tolerated (preferably in a seated or supine position)

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Isometric activation of the peroneus longus, brevis and tertius
- Isotonic dorsiflexion and plantarflexion through a protected range of motion (10° of dorsiflexion and 30° of plantarflexion)

Sensorimotor Exercises

- Seated active plantarflexion to 30° and dorsiflexion to 10° using a rockerboard (see Figure 39-11)

Techniques to Increase Muscle Strength, Power, and Endurance

- Multi-angle isometrics to 10° dorsiflexion and 30° of plantarflexion

Neuromuscular Dynamic Stability Exercises

- Rhythmic stabilization in all directions (dorsiflexion, plantarflexion, inversion, and eversion)

Functional Exercises

- Ambulation in cam walker

TIMELINE 39-2 **Postoperative Rehabilitation After Lateral Ankle Ligament Reconstruction/Repair (Brostrom Procedure)**

PHASE I (weeks 1 to 2)	PHASE II (weeks 2 to 6)
• Splint for protection of surgical repair • Non–weightbearing with crutches • PT modalities to reduce pain and swelling • Active range of motion for the ipsilateral hip, knee and digits • Upper body ergometry for cardiovascular fitness	• Cam walking boot • Weightbearing as tolerated without assistive device • PT modalities to reduce pain and swelling • Neuromuscular electrical stimulation to facilitate neuromuscular reeducation • Tarsometatarsal and intermetatarsal joint mobilization • Scar mobilization • Active assisted range of motion to at least 10° dorsiflexion and 30° plantarflexion • Isometric activation of the peroneus longus, brevis and tertius • Multiangle isometrics to 10° of dorsiflexion and 30° of plantarflexion • Seated active dorsiflexion to 10° and plantarflexion to 30° with rockerboard • Rhythmic stabilization in all directions (dorsiflexion, plantarflexion, inversion and eversion) • Upper body strengthening activities as tolerated (seated or supine)

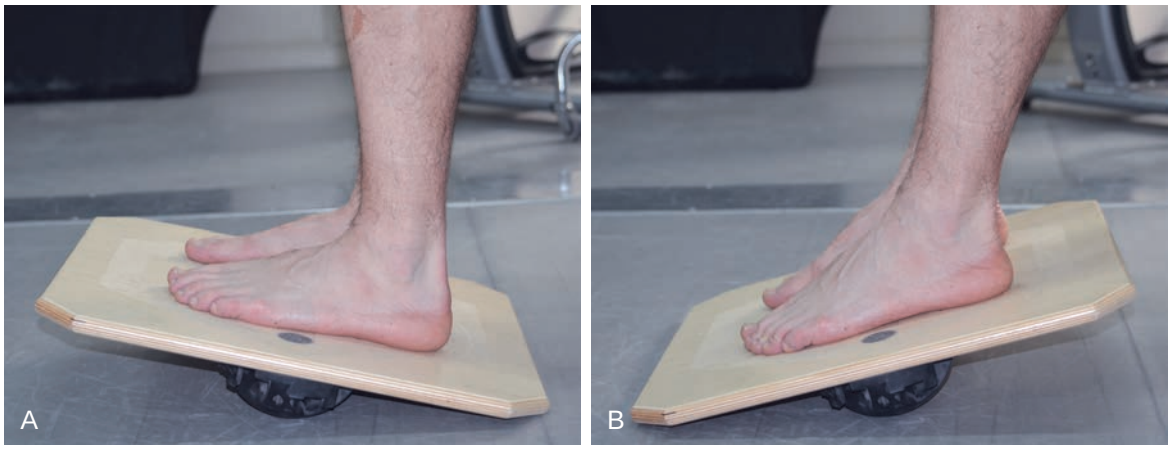

FIGURE 39-11 The rockerboard can be used in the initial stages of rehabilitation for reestablishment of dorsiflexion (**A**) and plantarflexion (**B**) in the operative ankle.

Milestones for Progression to the Next Phase

- Resolution of postoperative swelling
- No pain with full weightbearing and ambulation in cam walker
- Active range of motion to at least 10° of dorsiflexion and 30° of plantarflexion
- 3+/5 strength in the involved peroneus longus, brevis and tertius; gastrocnemius/soleus complex and tibialis anterior and posterior

Phase III: Immediate Postoperative Period (weeks 6 to 12)

Clinical Pearls

- The use of a treadmill for gait training can be effective in facilitating the normalization of the patient's gait pattern and ambulatory cadence.
- Ensure supplementation of the patient's outpatient treatment course with a comprehensive home exercise program of progressive range of motion and strengthening exercises.

TIMELINE 39-2 Postoperative Rehabilitation After Lateral Ankle Ligament Reconstruction/Repair (Brostrom Procedure) (Continued)

PHASE III (weeks 6 to 12)	PHASE IV (weeks 12 to 16)	PHASE V (weeks 16 to 24)
• Discontinue cam walking boot • Transition into lace-up figure-8 ankle brace • PT modalities as needed to reduce residual pain and swelling • Advance to full active range of motion in all directions • Mobilizations as needed to address particular motion restrictions • Scar mobilization as needed • Standing BAPS exercise: level 1 or 2 • Single-limb static standing balance on firm surface • Sagittal and coronal plane weightshifting on rocker board • Multi-directional ankle strengthening with resistance band • Double-limb calf press (body weight only) • Rhythmic stabilization in all directions • Single-limb standing on affected leg while pulling against resistance band with unaffected leg (sagittal plane) • Wall squats • Single-limb stepping (4″ step) • Treadmill walking • Stationary cycling	• PT Modalities as needed • Continue use of lace-up figure-8 brace • Mobilizations as needed • Double-limb and single-limb leg press • Shallow and deep water exercise or swimming • Upper body strengthening activities as tolerated • Stationary cycling • Standing BAPS exercise: level 3 or 4 • Single-limb static standing balance on foam mat • Single-limb standing balance on wobble board or disc • Double-limb and single-limb calf press • Resisted lunges • Lunges onto BOSU • Single-limb balance with Plyoball toss (front facing) • Medicine ball toss standing on wobble board with wide base of support • Single-limb standing on affected leg on foam mat while pulling against resistance band with unaffected leg (four directions) • Interval running	• Maintain full motion of ankle and all uninvolved joints • Mobilizations as needed • Advance weight/resistance as tolerated for previous OKC and CKC exercises • Treadmill running • Elliptical trainer for cross training • Standing BAPS exercise: level 3 or 4 • Single-limb static standing balance on foam mat with perturbation such as multidirectional reaching • Resisted lunges onto BOSU • Single-limb balance with Plyoball toss (side facing) • Medicine ball toss standing on wobble board with narrow base of support • Box jumps • Double-limb and single-limb plyometric hops • Straight line sprints • Shuttle run • Crossover and cutting drills • Sport specific drills

Goals

- Transition to full weightbearing in lace-up figure-8 ankle brace
- Advance to full active range of motion in all directions
- Increase strength in the involved peroneus longus and brevis, gastrocnemius/soleus complex and tibialis anterior and posterior to 4/5
- Normalize gait pattern and ambulatory cadence
- Initiate single-limb activities for strength, balance and proprioception training

Protection

- Lace-up figure-8 ankle brace

Management of Pain and Swelling

- Oral analgesic medication or NSAIDs as needed.
- Ice and elevation following physical therapy and other periods of prolonged standing and/or walking
- Commercially available sequential compression cryotherapy devices may be used to further control and reduce swelling

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Tarsal, tarsometatarsal, and intermetatarsal joint mobilization as needed to address particular mobility restrictions.

Soft Tissue Techniques

- Scar mobilization as needed

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Active assisted range of motion exercises through the normal range of motion in all directions. Care must be taken not to advance beyond the normal ligamentous endfeel of the surgically repaired anterior talofibular and calcaneofibular ligaments in dorsiflexion, plantarflexion or inversion.

FIGURE 39-12 Standing Biomechanical Ankle Platform System (BAPS) board. The patient rotates the board in both clockwise and counterclockwise directions. The BAPS system incorporates an adjustable half-dome base by which the degree of motion and instability can be advanced (Levels 1 to 5). Refer to postoperative phases for appropriate advancement of levels.

Other Therapeutic Exercises

- Stationary cycling
- Upper body strengthening activities as tolerated (preferably in a seated or supine position)

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Peroneus longus, brevis and tertius

Sensorimotor Exercises

- Standing Biomechanical Ankle Platform System (BAPS) exercise: clockwise and counterclockwise, level 1 or 2 (Figure 39-12)

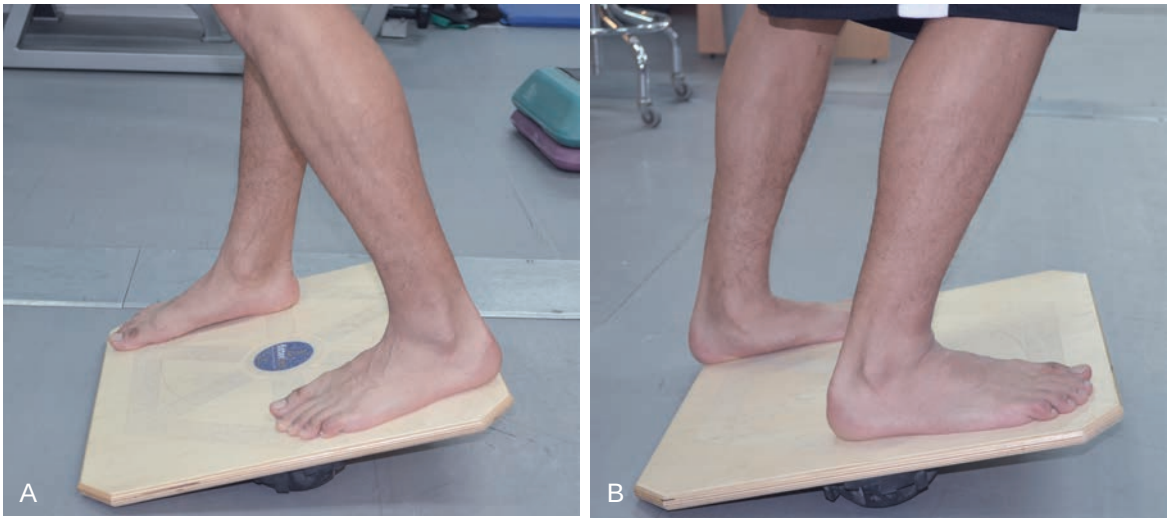

FIGURE 39-13 Sagittal plane weight shifting on a rockerboard isolating ankle plantarflexion (**A**) and dorsiflexion (**B**). Coronal plane weight shifting for eversion and inversion can also be incorporated utilizing the rockerboard.

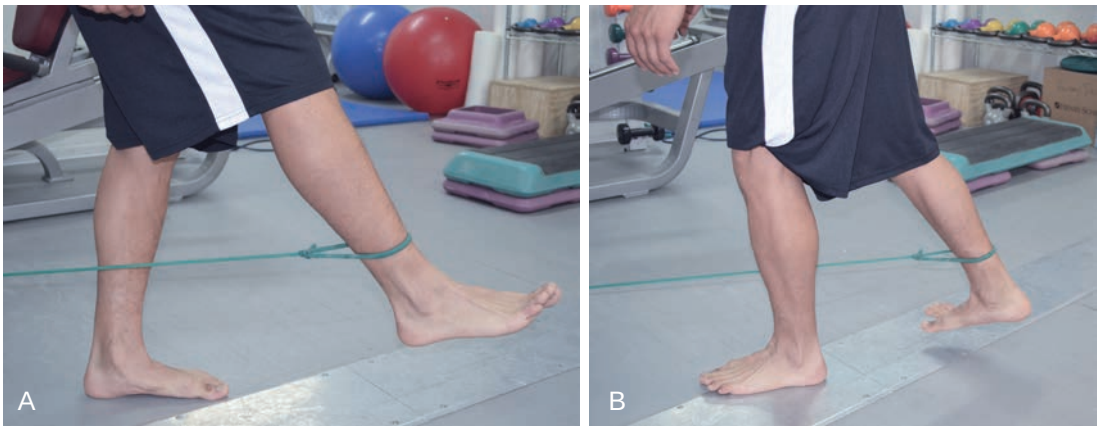

FIGURE 39-14 Resisted hip flexion (**A**) and extension (**B**) while standing on single limb. These exercises can also be advanced to standing on a foam mat with the single limb.

- Single-limb static standing balance on firm surface
- Sagittal and coronal plane weight shifting on rocker board (Figure 39-13)

Open and Closed Kinetic Chain Exercises

- (OKC) Multi-directional ankle strengthening with resistance band
- (CKC) Double-limb calf press (body weight only)

Techniques to Increase Muscle Strength, Power, and Endurance

- Treadmill walking

Neuromuscular Dynamic Stability Exercises

- Rhythmic stabilization in all directions
- Single-limb standing on operative leg while pulling against resistance band with nonoperative leg (sagittal plane) (Figure 39-14)

Functional Exercises

- Wall squats
- Single-limb stepping (4″ step)

Milestones for Progression to the Next Phase

- Full active range of motion in all directions
- Strength in the involved peroneus longus, brevis and tertius; gastrocnemius/soleus complex and tibialis anterior and posterior to 4/5
- Normal gait pattern and ambulatory cadence

Phase IV (weeks 12 to 16)

Clinical Pearls

The use of a structured return to running program utilizing intervals is essential for minimizing injury risk and facilitating safe progression. Refer to the sample program in Box 39-2. The patient is advanced to the next stage when the running intervals are performed without pain and with a normal running pattern.

BOX 39-2 Sample Structured Return to Running Program

STAGE	WALK	RUN	REPETITIONS	TOTAL TIME
Stage 1	5 minutes	1 minute	5	30 minutes
Stage 2	4 minutes	2 minutes	5	30 minutes
Stage 3	3 minutes	3 minutes	5	30 minutes
Stage 4	2 minutes	4 minutes	5	30 minutes
Stage 5	1 minute	5 minutes	5	30 minutes

The patient is advanced to the next stage when the running intervals are performed without pain and with a normal running pattern.

Goals

- Increase strength in the involved peroneus longus, brevis and tertius; gastrocnemius/soleus complex and tibialis anterior and posterior to at least 4+/5
- Equal static single-limb standing balance bilaterally
- Ability to perform all rehabilitation activities without bracing
- Return to straight-line running

Protection

- Use of lace-up figure-8 ankle brace as needed during periods of prolonged ambulation especially on uneven terrain.

Management of Pain and Swelling

- OTC analgesics or NSAIDs as needed
- Ice as needed following rehabilitation activities or when residual swelling is noted

Other Therapeutic Exercises

- Double-limb and single-limb leg press
- Shallow and deep water exercise or swimming (if aquatics are available)

FIGURE 39-15 Static single-limb standing balance for the operative extremity utilizing foam mat.

FIGURE 39-16 Single-limb standing balance on wobble board.

- Upper body strengthening activities as tolerated
- Stationary cycling

Sensorimotor Exercises

- Standing BAPS exercise: clockwise and counterclockwise, level 3 or 4
- Single-limb static standing balance on foam mat (Figure 39-15)
- Single-limb standing balance on wobble board or disc (Figure 39-16)

Open and Closed Kinetic Chain Exercises

- (CKC) Double-limb and single-limb calf press (Figure 39-17)
- (OKC) Multi-directional ankle strengthening utilizing a commercially available weighted device such as the Ankle Isolator® (Figure 39-18)

Techniques to Increase Muscle Strength, Power, and Endurance

- Resisted lunges (Figure 39-19)

FIGURE 39-17 Single-limb Closed Kinetic Chain (CKC) calf press. This can also be performed in double-limb support.

Neuromuscular Dynamic Stability Exercises

- Lunges onto BOth Sides Up (BOSU)® (Figure 39-20)
- Single-limb balance with Plyoball toss (front facing) (Figure 39-21)
- Plyoball toss standing on wobble board with wide base of support

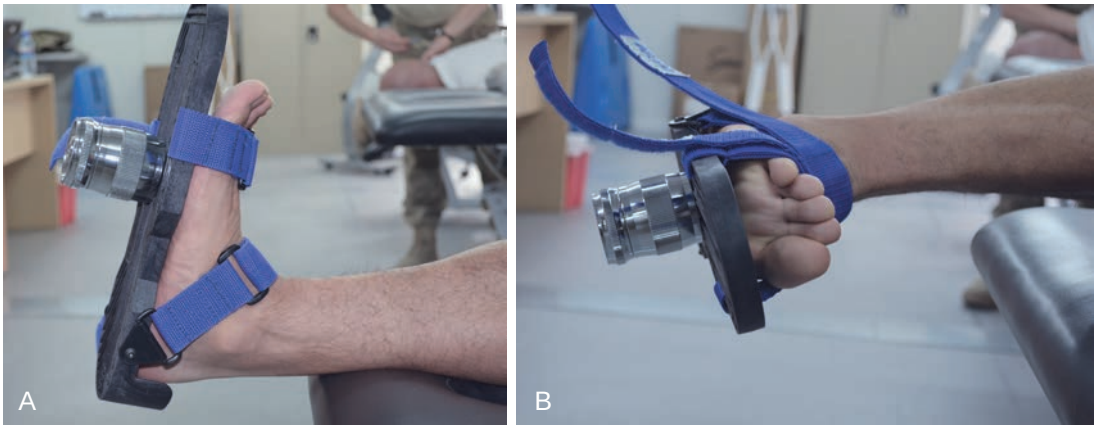

FIGURE 39-18 Resisted Open Kinetic Chain (OKC) ankle dorsiflexion (**A**) and eversion (**B**). Shown is a commercially-available weighted foot platform that can be used to strengthen the tibialis anterior and peroneal muscles respectively.

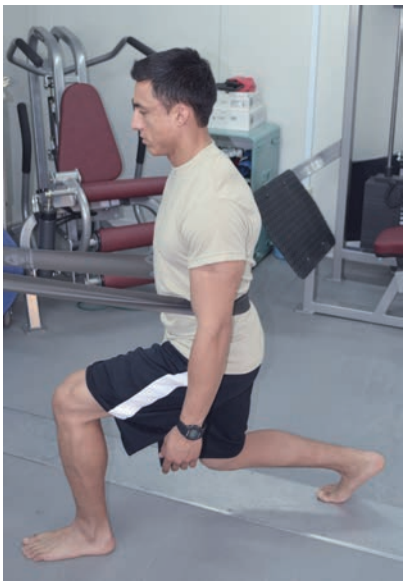

FIGURE 39-19 Resisted lunges. Patient should alternate leading with the operative and nonoperative extremity.

- Single-limb standing with operative leg on foam mat while pulling against resistance band with nonoperative leg (four directions) (Figure 39-22)

Functional Exercises

- Single-limb step

Milestones for Progression to the Next Phase

- Strength in the involved peroneus longus, brevis and tertius; gastrocnemius/soleus complex and tibialis anterior and posterior equals 4+/5
- Equal static single-limb standing balance bilaterally
- Ability to perform all rehabilitation activities without bracing

Phase V (weeks 16 to 24)

Goals

- Increase strength in the involved peroneus longus, brevis and tertius; gastrocnemius/soleus complex and tibialis anterior and posterior to 5/5
- Equal dynamic single-limb standing balance bilaterally
- Engage in sport-specific training
- Straight-line running at full speed without limitations
- Full speed cutting and crossover without limitations
- Fully controlled rapid deceleration, stopping and starting activities
- No limitations in jumping or landing activities
- Return to full sports participation

Protection

- Lace-up figure-8 ankle brace for sports and activities that require rapid stops/starts and/or changes in direction (i.e., cutting)

Management of Pain and Swelling

- OTC analgesic medication or NSAIDs as needed
- Ice as needed

Other Therapeutic Exercises

- Double-limb and single-limb leg press
- Shallow and deep water exercise or swimming (if aquatics are available)

FIGURE 39-20 Lunges onto BOSU facing forward (**A**) and to the side (**B**).

FIGURE 39-21 Single-limb balance on foam mat with Plyoball toss (front facing). This exercise can also be performed with double-limb support if patient is unstable in single-limb stance.

- Upper body strengthening activities as tolerated
- Stationary cycling
- Use of the elliptical trainer for cross training

Sensorimotor Exercises

- Standing BAPS exercise: clockwise and counterclockwise, level 4 or 5
- Single-limb standing balance on foam mat with perturbation such as multi-directional reaching (Figure 39-23)
- Single-limb standing balance on wobble board or disc

Open and Closed Kinetic Chain Exercises

- Advance weight/resistance as tolerated for previous OKC and CKC exercises

Techniques to Increase Muscle Strength, Power, and Endurance

- Straight-line sprints
- Shuttle run
- Crossover and cutting drills

Neuromuscular Dynamic Stability Exercises

- Resisted lunges onto BOSU® (See Figure 39-20)
- Single-limb balance with Plyoball toss (side facing)
- Medicine ball toss standing on wobble board with narrow base of support
- Single-limb standing on affected leg on foam mat while pulling against resistance band with unaffected leg (four directions)

Plyometrics

- Shuttle® System
- Box jumps
- Two-leg ankle hops: in place
- Two-leg ankle hops: forward/backward
- Two-leg ankle hops: side to side
- Unilateral ankle hops: in place
- Unilateral ankle hops: forward/backward
- Unilateral ankle hops: side to side
- Unilateral broad jump

Functional Exercises

- Single-limb stepping (6″ step)
- Running

Sport-Specific Exercises

- Practice of key elements of the patient's particular sport/event

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- Strength in the involved peroneus longus, brevis and tertius; gastrocnemius/soleus complex and tibialis anterior and posterior equals 5/5
- Equal dynamic single-limb standing balance bilaterally

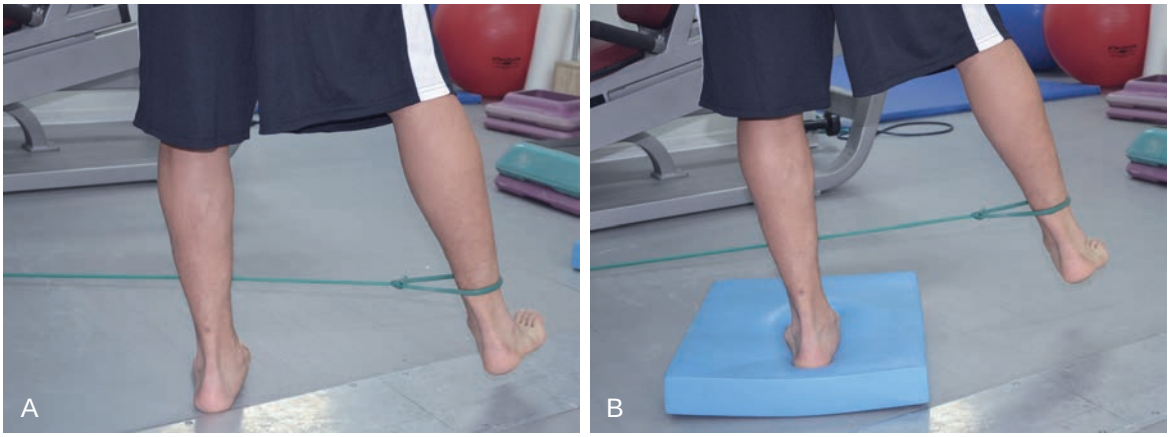

FIGURE 39-22 Single-limb standing on affected leg off (**A**) and on (**B**) a foam mat while pulling against resistance band with unaffected leg (hip flexion, extension, abduction and adduction).

FIGURE 39-23 Single-limb standing balance on foam mat with perturbation such as multi-directional reaching for a weight.

- Return to running without limitations
- Return to sports without limitations

Criteria for Return to Sport

General

- Full active range of motion in the operative ankle
- Normal (5/5) strength in the musculature in the operative ankle
- Straight-line running at full speed without limitations
- Full speed cutting and crossover drills
- No limitations in jumping or landing activities

Sport-Specific

- With respect to return to sport criteria for specific sports, the rehabilitation specialist must analyze the physical demands of the respective sport on the ankle and employ a series of tests and exercises to ensure readiness for return to pre-injury levels of activity.

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Continue to maximize lower extremity strength with particular attention on the peroneals
- Continue to maximize balance and proprioception with ongoing perturbation training

Exercises and Other Techniques for Prevention of Recurrent Injury

- Employ cross-training techniques to minimize the risk of overuse injury
- Continue with bracing during high-level sports

Evidence

Kannus P, Renstrom P: Treatment for acute tears of the lateral ligaments of the ankle. Operation, cast, or early controlled mobilization. *J Bone Joint Surg Am* 73:305–312, 1991.

In this current concepts review, 12 prospective randomized studies are assessed in order to find the optimal treatment for grade III (complete) lateral ligament sprains. Of the three treatment modalities, the authors conclude that functional rehabilitation of acute sprains is superior to acute surgical repair or cast immobilization alone. Functional rehabilitation offers the earliest return to work and sports with maintenance of excellent range of motion, and avoids surgical complications. Furthermore, patients with persistent instability after functional rehabilitation do well with delayed surgical repair. (Level I evidence).

Karlsson J, Rudholm O, Bergsten T, et al: Early range of motion training after ligament reconstruction of the ankle joint. *Knee Surg Sports Traumatol Arthrosc* 3:173–177, 1995.

In a prospective, randomized study, 40 patients were randomized postoperatively after lateral ankle ligament repair to cast immobilization for 6 weeks or early range of motion in a walker boot at 2 weeks. Both groups then began the identical postoperative therapy regimen. The early mobilization group had less sick leave (6.5 vs. 8.5 weeks for the cast group) and an earlier return to sports (9.5 vs. 12.5 weeks). At 2 years final follow-up, 80% of the cast-immobilized patients were deemed to have satisfactory results on the scoring scale used versus 90% for the early range of motion group. (Level I evidence).

Kaumeyer G, Malone TR: Ankle injuries: anatomical and biomechanical considerations necessary for the development of an injury prevention program. *J Orthop Sports Phys Ther* 1:171, 1980.

The authors review the anatomy and biomechanics of the ankle joint and make recommendations on an injury prevention program for athletes returning to play after an ankle sprain. (Level V evidence).

Kirk KL, Campbell JT, Guyton GP, et al: ATFL elongation after Brostrom procedure: a biomechanical investigation. *Foot Ankle Int* 29:1126–1130, 2008.

In a cadaveric study, the anterior talofibular ligaments of six specimens were meticulously dissected. A differential variable reluctance transducer (DVRT) was attached to the ligament endpoints and the ligament lengths were examined pre- and postrepair. Elongation was measured in a load frame with protected motion of 30° plantarflexion and 10° dorsiflexion for the intact and sectioned ATFL and for the repaired specimen with and without protected motion. Initial elongation in the unprotected, repaired group was significantly higher than initial elongation in the intact ($p < 0.01$), sectioned ($p = 0.02$), and repaired, protected ($p < 0.01$) groups. Final elongation in the unprotected repaired group was also greater than final elongation in all other groups ($p < 0.01$ for all comparisons). This study provides biomechanical support for protected plantarflexion and dorsiflexion range of motion protocols after lateral ankle ligament reconstruction.

Lee AJ, Lin WH: Twelve-week biomechanical ankle platform system training on postural stability and ankle proprioception in subjects with unilateral functional ankle instability. *Clin Biomech* 23:1065–1072, 2008.

In this therapeutic study, 12 university students with unilateral functional ankle instability underwent a 12-week biomechanical ankle platform training program. Baseline and posttraining measurements of static postural stability and ankle reposition sense were taken. The mean radius of the center of pressure excursion recorded during single-leg standing with a force platform (an indicator of static postural instability) was significantly reduced after the 12-week training program ($p < 0.05$). The absolute error from a preselected ankle angle as measured by an isokinetic dynamometer was also significantly reduced after the training program, indicated an improvement in ankle reposition sense ($p <$

0.05). This study lends support to the notion that as ankle proprioception (position sense) improves with training, so does functional joint stability. (Level II evidence).

Lentell G, Baas B, Lopez D, et al: The contributions of proprioceptive deficits, muscle function, and anatomic laxity to functional instability of the ankle. *J Orthop Sports Phys Ther* 21:206–215, 1995.

Forty-two subjects with unilateral chronic ankle instability were evaluated in order to quantitate the role of decreased proprioception, eversion weakness and anatomic laxity of the unstable ankle versus the contralateral normal ankle. Analysis revealed a significant difference in proprioception and radiographic laxity in the chronically unstable ankles compared to the opposite normal ankles. Ankle eversion isokinetic strength differences were not significant. The authors conclude that proprioception and anatomic laxity play the greatest roles in contributing to the chronically unstable ankle, and thus should be the focus of treatment. (Level III evidence).

Li X, Killie H, Guerrero P, et al: Anatomical reconstruction for chronic lateral ankle instability in the high-demand athlete: functional outcomes after the modified Brostrom repair using suture anchors. *Am J Sports Med* 37:488–494, 2009.

In this case series, 52 patients, all high-level athletes, were followed after a lateral ankle ligament repair (modified Brostrom) with the use of modern suture anchors. The postoperative therapy protocol is documented. At final follow-up at 2 years after the index surgery, 94% had returned to their preoperative level of sporting activity (Tegner scores) and the mean Karlsson score for ankle function was 95 (possible 100 points). Only 6% of patients had decreased motion of the ankle, and there was a 6% rerupture rate, all occurring more than one year after surgery in competitive sports. The authors conclude that anatomical surgical reconstruction utilizing suture anchors with early mobilization postoperatively is associated with a return to previous sporting level in high-level athletes. (Level IV evidence).

Pijnenburg AC, Van Dijk CN, Bossuyt PM, et al: Treatment of ruptures of the lateral ankle ligaments: a meta-analysis. *J Bone Joint Surg Am* 82:761–773, 2000.

The authors conducted a meta-analysis of available randomized controlled trials comparing operative treatment, functional treatment and cast immobilization after grade III lateral ligament sprains of the ankle. Twenty-seven studies were included in the review. The authors conclude that operative treatment was associated with a lower risk of recurrent instability than functional treatment, although with the associated risks of operative complications. Furthermore, operative treatment followed by brief immobilization (3 weeks) followed by functional treatment was associated with better results than 6 weeks of postoperative cast immobilization followed by functional treatment. (Level I evidence).

Sefton JM, Yarar C, Hicks-Little CA, et al: Six weeks of balance training improves sensorimotor function in individuals with chronic ankle instability. *J Orthop Sports Phys Ther* 41:81–89, 2011.

In this prospective cohort study, 12 patients with chronic ankle instability (CAI) and 9 healthy volunteers were studied. The patients with CAI received a 6-week balance training program while the healthy subjects did not. At the end of 6 weeks, the CAI patients posttraining demonstrated enhanced dynamic balance (anteromedial direction $p = 0.021$, medial direction $p = 0.048$, posteromedial direction $p = 0.030$), improved inversion joint position sense, and beneficial changes in motoneuron pool excitability compared to healthy controls who did not train. No systematic differences were detected for static balance or plantar flexion joint position sense tasks. (Level II evidence).

Multiple-Choice Questions

QUESTION 1. Name the two lateral ankle ligaments that are most commonly responsible for chronic lateral ankle instability to inversion and are tested manually by the anterior drawer test and the talar tilt test.

A. Posterior talofibular ligament and calcaneofibular ligament
B. Deltoid ligament and subtalar interosseus ligament
C. Anterior talofibular ligament and calcaneofibular ligament
D. Anterior tibiofibular ligament and posterior tibiofibular ligament

QUESTION 2. Common concomitant surgical procedures on patients with lateral ankle instability in addition to a Brostrom (lateral ankle ligament repair/reconstruction) include all the following except:

A. Peroneal repair, debridement, or tenodesis
B. Posterior tibial tendon reconstruction or repair
C Hindfoot osteotomy for excessive heel varus
D. Ankle arthroscopy with or without osteochondral lesion of the talus treatment

QUESTION 3. In an early range of motion therapy protocol in the 2- to 6-week period, rehabilitation goals for this period include all the following except:

A. Dorsiflexion to at least 10° and plantarflexion to 30°
B. Increase active inversion to 20°
C. Increase strength in peroneals, tibialis anterior and posterior to at least 3+/5
D. Resolution of postoperative swelling

QUESTION 4. Return to straight-line jogging on an even surface after a Brostrom lateral ligament repair/reconstruction is appropriate at what postoperative phase or time point

A. Phase II (2 to 6 weeks)
B. Phase III (6 to 12 weeks)
C. Phase IV (12 to 16 weeks)
D Phase V (16 to 24 weeks)

QUESTION 5. In a landmark Level 1 study, Karlsson et al. in 1995 showed all of the following occurred with early motion at 2 weeks postoperatively versus immobilization until 6 weeks except:

A. Less sick leave (6.5 weeks versus 8.5 weeks) in the early motion group
B. A higher rate of "satisfactory" scores (90% versus 80%) in the early motion group
C. Earlier return to sports (9.5 weeks versus 12 weeks) in the early motion group
D. A higher failure / recurrent instability rate (24% versus 10%) in the early motion group

Answer Key

QUESTION 1. Correct answer: **C** (see Surgical Technique)

QUESTION 2. Correct answer: **B** (see Surgical Technique)

QUESTION 3. Correct answer. **B** (see Phase II Rehabilitation)

QUESTION 4. Correct answer. **C** (see Phase IV Rehabilitation)

QUESTION 5. Correct answer. **D** (see References)

POSTOPERATIVE REHABILITATION AFTER TREATMENT OF LATERAL AND MEDIAL ANKLE FRACTURES

Joseph M. Miller, PT, DPT, OCS, SCS, CSCS, and Brett D. Owens, MD

Indications for Surgical Treatment

- It has been reported that between 15% to 25% of all athletic injuries are to the ankle.[1-5] During athletic performance the foot and ankle absorbs significant stress in a multitude of directions. Forces transmitted through the ankle can reach up to six times the body weight during dynamic activity. These large forces imparted across the ankle occasionally lead to fracture and/or ligament disruption. Approximately 5.2% of high school athletes in the United States were diagnosed with ankle fractures from 2005 to 2006.[6] Fractures and/or ligament disruption of the ankle can result in long-term disability and greatly impede or prevent return to sports. Because of the stresses and potential for disability, stabilization and complete healing are essential for medial and lateral fractures and/or ligament disruptions of the ankle.
- Anatomic reduction of the ankle joint is the primary factor that determines long-term success of treatment, regardless of the intervention method.[2,4,6] Fracture type, joint surface alignment, age of the person and presence of cartilage injury also influence long-term outcomes.[4] Three-view radiographs (A/P, lateral, and mortise view) are utilized to assess displacement. Stress views are indicated for suspected ligamentous and syndesmosis injuries. Medial clear space has been shown to be a reliable indicator of instability in the ankle joint.[3] Nonoperative criteria are minimal displacement and stability of fracture/joint.[3] Nonoperative management routinely consists of immobilization in a hard cast or removable splint. Nonoperative immobilization and healing times range from 6–12 weeks.[1-3,5]
- Operative management of ankle fractures and/or ligament disruptions offer the potential for quicker recovery, increased stabilization and better alignment. Additionally, fixation may be indicated if nonoperative care fails for certain injuries. Indications for operative treatment are specific to each type of injury.[2] For isolated lateral malleolar fractures displacement greater than 2 to 4 mm, significant external rotation or shortening of the fibula are indications for surgical stabilization. For displacements of 2 to 4 mm, operative fixation may be offered when the athlete prefers a quicker return to sport. Bimalleolar fractures or equivalent are inherently unstable injuries and require reduction and fixation. Instability of the syndesmosis is diagnosed by assessing the cartilage interval between the medial talus and medial tibia while applying external rotation stress to the ankle.[3] This interval should be no more than 2 mm greater than the interval between the distal tibia and proximal talus. Syndesmotic injuries that are unstable on radiographs or fluoroscopy require fixation across the tibiofibular joint.

Return to Sport

Return to sport after unstable ankle repair is challenging due to the large forces that the ankle joint must endure in most athletic competitions. Also, time frames for return to competition and adequate healing are not consistent across the age range of athletes. There are a limited number of studies that have investigated return to sports after unstable ankle injuries.[1-3,5] However, predictors of return to sport at 1 year have been reported.[1] They include: younger age, male gender, mild to no systemic disease and less severe ankle fractures. Syndesmosis injuries are especially complicated and require longer recovery times. It has been shown the 4.5 mm cortical screws have provided sufficient stabilization of the syndesmosis in young healthy athletes and allowed return to sports as quickly as 6 weeks without complications.[3,5] Additionally, young healthy athletes with bimalleolar or equivalent injuries who underwent stabilization surgeries have been able to return to competition on average of 13 weeks. Eighty-eight percent of healthy older (average age 35 years old) recreational athletes have been able to return to competition within 1 year of stabilization surgery versus only 11% of competitive sport athletes.[1] Despite the age disparity in return to sport time frames, operative repair with immediate progressive weightbearing and progressive functional rehabilitation have allowed for safe and complete return to competition.[1,2,4,5]

Major Surgical Steps

- Anatomic reduction of malleolar fractures
- Rigid internal fixation
- Assessment of syndesmotic injury
- Reduction and fixation of syndesmotic injury

Factors That May Affect Rehabilitation

Surgical

- Lateral malleolus ORIF only versus bimalleolar ORIF versus malleolus + syndesmotic fixation
- Tibial plafond or talus involvement
- Rigidity of fixation construct and quality of patient bone

Other Surgical Techniques and Options

Appropriate surgical treatment of ankle fractures in athletes is facilitated by early evaluation of these injuries. Plain radiographic assessment guides surgical treatment and rehabilitation, therefore is the first recommended step. If easily accessible, radiographs should be obtained before any reduction maneuver. However, if not readily accessible, any joint deformity should be urgently reduced in order to preserve vascularity to the foot and relieve tension of the neurologic structures and soft tissues. The three standard radiographic views are used: AP, lateral, and mortise (Figure 39-24*A*). The mortise view is essential to evaluate the relationship between the tibia, fibula, and talus. As mentioned previously, fracture displacement greater than 2 mm is an indication for surgery, as well as syndesmotic disruption. An argument could be made for earlier return-to-play for nondisplaced fractures treated with rigid fixation; however, there is no literature to support this approach.

The timing of surgery is critical. The healing process does not begin for the bone until ORIF is performed as any clot is typically removed to facilitate anatomic reduction. Therefore, early fixation means earlier return to sport. If fractures are evaluated within minutes to hours, emergent surgery can be performed. This is necessary in cases of fracture dislocations or open injuries. However, if not possible within 12 hours, swelling may preclude the surgeon's ability to safely manage the soft-tissues and surgery may be delayed for 3 to 7 days until swelling improves.

Delicate handling of the soft tissues is critical, but adequate incision is necessary to ensure visualization of the fracture. Anatomic reduction is achieved and fixation is performed. We typically recommend interfragmentary screw fixation using lag technique and 3.5-mm cortical screws. Two screws orthogonal to the fracture line may be enough for rigid fixation, but a low threshold should exist for supplementary plate fixation in athletes attempting an early return to sport. We prefer use of 1/3 semitubular plates due to their low-profile. Syndesmosis integrity may then be tested with an external rotation stress in the mortise position under fluoroscopy. If a question of the syndesmotic integrity exists, we prefer 4.5-mm cortical screw fixation but have also used suture and button constructs. Postfixation radiographs ensure adequacy of reduction and hardware position and provide a comparison view for future radiographs (Figure 39-24*B*).

The soft-tissues are closed in layers and the patient is placed into a splint. This splint is maintained for 1 to 2 weeks and removed for wound check and suture removal (Figure 39-25). At this time, the patient is placed into a cast-boot, allowing for range-of-motion of the ankle to begin.

Before Surgery: Overview of Goals, Milestones, and Guidelines

To Minimize Debilitation and Atrophy

- **Exercises:** For ankle fractures/ligament disruptions, immobilization to protect the area is of key

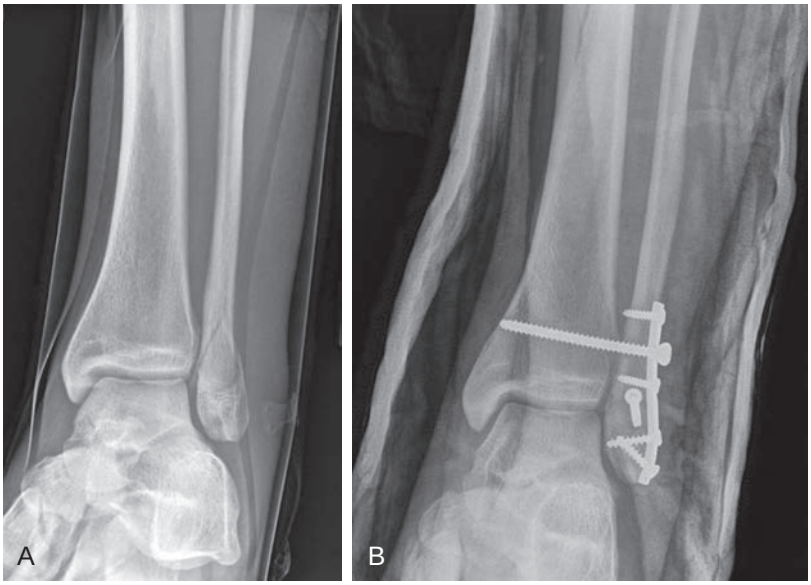

FIGURE 39-24 A, A mortise preoperative view; **B,** a mortise postoperative view.

FIGURE 39-25 Two weeks after suture removal.

importance. Minimizing direct stress to the area in order to avoid displacement and complications should also be a priority before surgery. Maintaining strength and ROM of the hip and knee should be addressed only if external stabilization of the ankle is sufficient. Timely surgical intervention is also important to minimize atrophy.
  - Supervised: Quad sets, four-way straight leg raise, knee and hip AROM, gait nonweightbearing with crutches
  - Home: Nonweightbearing with crutches
- **Modalities:**
  - During treatment: Compression and cryotherapy device use
  - Home use: Ice with elevation three to five times daily for 20 minutes; compression; stabilization with Aircast or similar splint

To Relieve Disability of Injury

- **Acute injury**
  - Exercise Hip ROM and knee ROM
  - Modalities Ice, compression, elevation and immobilization

Phase I: Immediate Postoperative Period (days 0 to 14)

Protection

- Postoperative immobilization is achieved via short leg cast (changed at 7 days if necessary)
- Toe touch weightbearing with bilateral crutches

Management of Pain and Swelling

- Oral pain medication as prescribed
- Application of ice (if feasible)
- Elevation of the limb at rest
- Patient education to minimize lower extremity time in the dependent position
- Casting provides swelling control
- Additional instruction of elevation and avoiding the dependent position

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- AROM Knee and hip
- Hamstring stretching with an assistive strap

Other Therapeutic Exercises

- Athletes are encouraged to participate in upper body ergometry as tolerated five times a week for cardiovascular conditioning
- Four-way straight leg raise, short arc quadriceps, prone hamstring curls
- All strengthening should be done starting with low resistance (TheraBand or ankle weight), high repetitions, and nonpainful range of motion

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- AROM phalanges to mitigate stiffness, increased muscle pumping action of fluid and activation of foot musculature while immobilized in the cast

Milestones for Progression to the Next Phase

- Goals of the immediate postoperative phase:
  - Protection of repaired structures
  - Minimize effects of immobilization
  - Decrease pain and inflammation
- Progression to the next phase
  - Primarily time based—dependent on the quality of surgical fixation and specific structures repaired

Phase II (weeks 3 to 6)

Goals

It has been shown that immobilization of the ankle for as little as 2 weeks can cause significant atrophy and weakness of the posterior and anterior muscle of the lower leg.[7] In the first 2 weeks after immobilization, the cross-sectional area (CSA) of the posterior compartment decreased by 14% and the anterior compartment by 10%. After an additional 5 weeks, the posterior compartment CSA was a total of 24% less and the anterior compartment was a total of 19% less. Typically, wasting of the musculature is noted when compared to the contralateral side (Figure 39-26). An additional finding was that specific torque of the plantar flexors was also significantly lower in the immobilization group versus matched

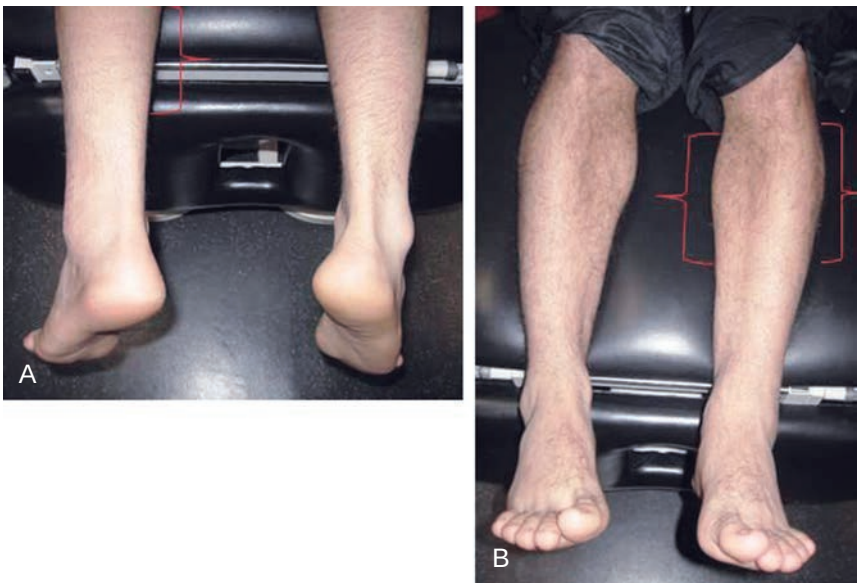

FIGURE 39-26 Atrophy of the left leg is denoted by the brackets.

controls (59% decrease in torque production immediately after immobilization versus matched controls).[7]

Progressive weightbearing, endurance, and resistance exercises have been shown to improve strength and girth measurements after a period of immobilization.[7-10] Plantar flexion specific torque also improved over the 10-week period, but there was still a 5% deficit compared to the contralateral side and a 20% deficit compared to healthy controls.[7] Therefore, minimizing complete immobilization and initiating progressive strengthening, weightbearing, and endurance are the major goals of the rehabilitation during this timeframe. Additional goals include: normalizing gait, restoration of full pain-free movement and restoring proprioceptive input.

Protection

- Progress as tolerated based on symptoms and surgical fixation

Management of Pain and Swelling

- Oral medications as prescribed
- Therapeutic modalities for pain and muscle guarding to include: TENS, Hi-Volt, IFC, and ice
- Patient education: Using pillow or similar apparatus for elevation and positioning for comfort
- Cryotherapy and compression
  - Game ready, cryo cuff, cryo press, ice with compression wrap

TIMELINE 39-3 **Postoperative Rehabilitation after Treatment of Lateral and Medial Ankle Fractures**

PHASE I (weeks 0 to 2)	PHASE II (weeks 3 to 6)
• Short leg cast (changed at 7 days if necessary) • AROM knee and hip • 4-way straight leg raise, short arc quadriceps, prone hamstring curls • AROM phalanges	• Ace wrap with or without horseshoe padding once in camboot • PT Modalities • Scar mobilization once incisions have closed • Conservative to deep tissue techniques to gastocnemius, soleus and peroneals as needed • Stretching/flexibility techniques for the musculotendinous unit • AROM: plantar flexion and dorsiflexion as tolerated 2–3 weeks after surgery with inversion and eversion added at 3–4 weeks • PROM: plantar flexion and dorsiflexion as tolerated 2–3 weeks after surgery with inversion/eversion added at 3–4 weeks • Ankle circles and alphabet 3–4 weeks • Gastrocnemius/soleus stretching: 3–4 weeks with assisted stretching strap supine or long sitting, 4–5 weeks standing with contralateral leg forward • Plantar flexion and dorsiflexion submaximal Isometrics and light resistance 2–3 weeks • Toe crunch with towel as resistance as needed 2–3 weeks • Add inversion and eversion resistance with progression to maximal isometrics • Standing 4 way straight leg raise 5–6 weeks • Double leg tandem stance 4–5 weeks • Single leg stance 5–6 weeks

- Ace wrap with or without horseshoe padding once in camboot
- Continue to avoid the dependent position when not active

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

Manual therapy techniques may provide increased ROM in the ankle with relatively low risk of adverse effects.[5] ROM deficits in dorsiflexion have been shown to be positively affected by manual therapy.[5,12]

- **Precautions:**
- No active or passive eversion or inversion till 3 to 4 weeks
- Grade I–II mobilization Plantar flexion and dorsiflexion till 3 to 4 weeks then add Inversion/Eversion
  - Anatomical motion only 3 to 4 weeks
- Grade III mobilizations 5 to 6 weeks
  - Can add accessory joint manual therapy

Soft Tissue Techniques

- Scar mobilization once incisions have closed
- Conservative to deep tissue techniques to gastocnemius, soleus and peroneals as needed
- Stretching/flexibility techniques for the musculotendinous unit
- AROM: Plantar flexion and dorsiflexion as tolerated 2 to 3 weeks after surgery with inversion and eversion added at 3 to 4 weeks
- PROM: plantar flexion and dorsiflexion as tolerated 2 to 3 weeks after surgery with inversion/eversion added at 3 to 4 weeks
- Ankle circles and alphabet 3 to 4 weeks
- Gastrocnemius/Soleus stretching: 3 to 4 weeks with assisted stretching strap supine or long sitting, 4 to 5 weeks standing with contralateral leg forward

Other Therapeutic Exercises

- Hip strength Four-Way SLR add ankle weights
- Core strengthening
  - 3 weeks bent knee plank abdominal crunches and limb unsupported abdominal work
  - 4 to 6 weeks long leg planks, can progressively add limb supported abdominal work
  - Stability abdominal strengthening

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- 2 to 3 weeks
  - Plantar flexion and dorsiflexion submaximal Isometrics and light resistance
  - Toe crunch with towel as resistance as needed
- 3 to 4 weeks
  - Add inversion and eversion resistance with progression to maximal isometrics and progress resistance
- 5 to 6 weeks
  - Standing four-way straight leg raise

Sensorimotor Exercises

Proprioception has been theorized as a central processing of afferent sensory input from somatosensory, vestibular and visual inputs. Proprioception has been shown to be compromised with ankle injuries and after immobilization[3]. Training can improve dynamic and static instability and reduce the incidence of re-injury. Principles of proprioception training are:

- Progress from double leg to single leg
- Progress from single plane to multiplanar movements
- Progress from static to dynamic
- Progress from conscious focus balance to more automatic

TIMELINE 39-3 Postoperative Rehabilitation after Treatment of Lateral and Medial Ankle Fractures (Continued)

PHASE III (weeks 6 to 10)	PHASE IV (weeks 10 to 14)	PHASE V (weeks 15 to 21)
• Continue previous as needed • DC camboot to semirigid brace • Full AROM and PROM • PT modalities as needed • PROM-full • Mobilizations as needed • Lower stretching • Core strengthening/activation • Weightbearing strengthening • Light agility and begin walk/jog progression if appropriate • Light power training and sports specific	• Continue previous as needed • PT modalities as needed • PT manual therapy as needed • Stretching and mobility as needed • Progressive core activities • Olympic lifting • Progressive agility • Progress walk/jog to full jogging	• Mobilizations as needed • Progressive sports specific • Progress sprinting and agility • Progress to preinjury strength and Olympic training

- Decrease visual inputs
- Progress from basic to functional activities
- Double leg tandem stance 4 to 5 weeks
  - Progress from eyes open to eyes close tandem
  - Progress from even surface to uneven surface
  - Rebounder or ball toss with a partner progress from straight throw and catch to throw and catch with rotation
- Single leg stance 5 to 6 weeks
  - Progress from eyes open to eyes closed
  - Progress from even surface to uneven surface
  - Rebounder or ball toss with a partner progressing from straight throw and catch to throw and catch with rotation

Open and Closed Kinetic Chain Exercises

- CKC
  - Step-ups and step-downs at 3 to 4 weeks
  - Mini-squats 5 to 6 weeks
  - Shuttle MVP, leg press or equivalent 4 to 5 weeks (can initiate low level plyometrics with double leg to single depending on injury and healing)
  - Heel raise progression 5 to 6 weeks
- OKC
  - Leg curls, leg extensions 4 to 6 weeks
  - Ankle resistance with tubing 4 to 6 weeks all directions

Techniques to Increase Muscle Strength, Power, and Endurance

- Stationary bike light 3 weeks
- Aggressive stationary bike 4 weeks
- Elliptical trainer/stair stepper at 5 to 6 weeks
- Light jogging intervals (Table 39-1) 6 weeks with Aircast or equivalent (***depending on level of healing and fixation***) (Figure 39-27)

For muscle hypertrophy, power and endurance of any muscle group the following guidelines are recommended:

Table 39-1 Walk/Run Interval Performed Every Other Day on Track or Treadmill After Week 11 Progress Time by 10% a Week

Week	Walk	Jog	Repetitions	Total Time
6	4 min	2 min	5	30 min
7	3 min	3 min	5	30 min
8	4 min	2 min	5	30 min
9	5 min	1 min	5	30 min
10	5 min	10 min	2	30 min
11		15 min	1	15 min

- Hypertrophy
  - Volume: 3 to 5 sets of 6 to 12 reps with 1-minute rest between sets
  - Intensity: 60% to 80% 1 RM
  - Frequency 2 to 4 times a week
- Power
  - Volume 3 to 5 sets 1 to 5 reps with 2 to 3 minutes rest between sets
  - Intensity 30% to 60% 1RM
  - 1 to 2 times per week
- Endurance
  - Volume 2 to 5 sets 15+ reps with <90 seconds rest between sets
  - Intensity 50% to 65% 1RM
  - 3 to 5 times a week

Neuromuscular Dynamic Stability Exercises

- BAPS/ wobble board
  - 3 weeks seated
  - 4 to 6 weeks increased weightbearing
- Single-leg stance leg swings 5 to 6 weeks (Figure 39-28*A,B*)
- 4 to 6 weeks proprioception machine (cat eye balance, Proprio 5000, etc.)

FIGURE 39-27 Light jogging in an Aircast (*arrow*).

FIGURE 39-28 Single leg stance leg swings. **A,** Starting position is standing on the affected leg with the knee slightly bent. **B,** Swing the unaffected leg back and forth from the 5 o'clock position to the 11 o'clock position. Adjust swinging as needed.

1. Starting position is standing on the affected leg with the knee slightly bent
2. Swing the unaffected leg back and forth from the 5 o'clock position to the 11 o'clock position
3. Adjusting swinging as needed

Functional Exercises

- Gait training
  - Retro walk, side shuffle walk, back pedal walk, carioca walk, S-turns walk, etc. 4 to 5 weeks
  - Progress speed and add resistance to the above 5 to 6 weeks

Milestones for Progression to the Next Phase

- Normal gait, stair ambulation, full range of motion, ability to light jog with minimal pain (if cleared to jog)
- Additionally, should be able to perform walking agility drills without pain and difficulty
- Follow-up with surgeon for clearance to progress to the next phase

Note: Testing ankle flexibility in standing with standing dorsiflexion lunge test[3,12]

A strip of tape is placed perpendicular to a wall and the heel and big toe are aligned alongside the tape (Figure 39-29*A,B*). The patient's foot should be aligned so that the second toe and heel are kept perpendicular to the wall. The patient is instructed to not let the heel lose contact with the ground. The subject then lunges until the knee touches the wall. The distance is measured from the tip of the hallux to the wall.

Phase III (weeks 7 to 10)

Note: For older athletes the progress may need to be slowed due to slower rate of healing, this should be discussed amongst sports medicine team

Goals

Rehabilitation at this time should focus on progression toward athletic competition. Progressive strengthening should be continued with transition to more single leg activities. Functional testing should be incorporated before consideration of return to sport[3]. Return to sport can occur in a limited and minimal risk capacity for more severe ankle instability repairs (i.e., specialty players such as face-off man in lacrosse or long snapper in football can perform specialty then leave the field) or in almost normal capacity for isolated lateral malleolar fractures. The athlete should have stable hardware on three view radiographs and wear an Aircast equivalent even if returning in a limited capacity. Normalizing motor control, strengthening of supporting musculature for return to sport, conditioning of supporting musculature for return to sport, pain free plyometrics and able to initiate sports specific drills are the main goals for this timeframe.

Protection

- Aircast splint (especially if returning to competition) to ankle lace up brace

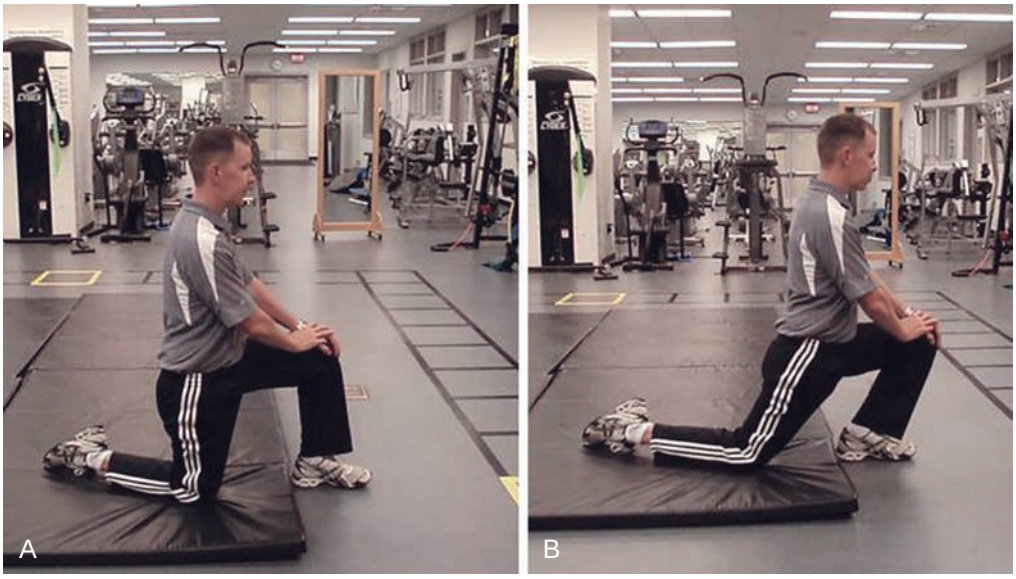
Management of Pain and Swelling

- Oral medications as needed
- Ice as needed
- Cryotherapy and compression

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Grade IV mobilizations: To include accessory motion of the ankle joint (A/P, P/A, Side glides, etc.)



1. Starting position is split kneeling with the affected leg forward
2. Place both hands on the knee of the affected lower extremity
3. Move the hips and trunk forwards as far as possible without lifting the heel
4. Hold in the forward position for 1-3 seconds
5. Repeat for repetitions as in dicated

FIGURE 39-29 Kneeling ankle dorsiflexion mobilization and soleus lengthening. **A,** Starting position is split kneeling with the affected leg forward. Place both hands on the knee of the affected lower extremity. **B,** Move the hips and trunk forwards as far as possible without lifting the heel. Hold in the forward position for 1 to 3 seconds. Repeat for repetition as indicated.

- Mobilizations with movement (MWM) in standing to increase weightbearing motion with a mobilization belt
  - Mulligan taping techniques may need to be incorporated in order to facilitate gains of motion
- Manual stretching as needed
- Self techniques
  - Single stance leg swings
  - Standing or kneeling dorsiflexion lunge rocking (Figure 39-30)

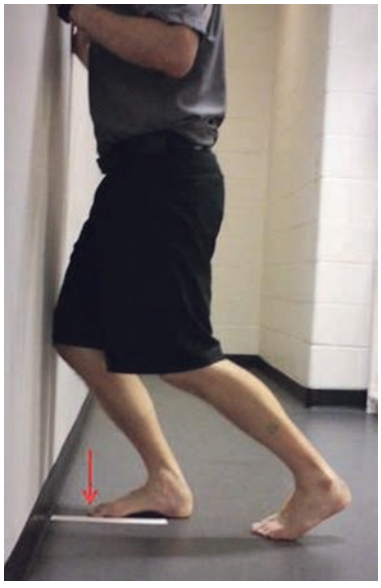


FIGURE 39-30 Standing dorsiflexion lunge rocking test. The red arrow is pointing to the tip of the hallux.

Soft Tissue Techniques

- Aggressive deep tissue techniques to gastroc, soleus and/or peroneals as needed
- More aggressive techniques such as ischemic release, foam roller, deep tissue massage and dry needling may be incorporated as needed.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Standing gastrocnemius stretch (add slant board or assist at 8 weeks)
- Standing soleus stretch (add slant board or similar assist at 8 weeks)
- Anterior tibialis stretch
- Progress to single leg

Other Therapeutic Exercises

- Upper body strengthening as prior to surgery
- Core strengthening
  - Full planks (front/sides/reverse)
  - Cable chops and lifts
  - Stability ball knee to chest, lateral rolls, and Russian twists
  - Medicine ball exercises
  - Turkish get up progression
  - Farmers walk or weight carry for development of hip stability

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Standing four-way SLR
- Isokinetic or isotonic strengthening plantarflexion, inversion, eversion and dorsiflexion

- Heel raise single leg
- Four-way strengthening with ankle isolator

Sensorimotor Exercises

- Double leg balance on foam to single leg
- Squatting or lunging on BOSU or half foam roller (double leg to single leg)
- Single leg clock reach with or without resistance
- Windmill toe touches in place

Open and Closed Kinetic Chain Exercises

- OKC
  - Leg curls: machine, TRX, slide board, stability ball, etc.
  - Hip strengthening four-way hip machine or TRX
- CKC
  - Step-ups with plantar flexion ipsilateral leg and contralateral knee high knee high
  - Double leg squat progressing to assisted single leg squat with devices such as the TRX, Cooke bands or similar

Techniques to Increase Muscle Strength, Power, and Endurance

- Romanian dead lifts for hip extension development (single leg)
- Push press for reeducation of triple extension
- Hang cleans with bar initially and progress for reeducation of triple extension
- Progress jogging program alternating with low impact activities such as stationary bike, swimming, elliptical or stair stepper
- Push-jerk

Neuromuscular Dynamic Stability Exercises

- Clock reach or Star Excursion Balance Test reaching
- Fitter, slide board or equivalent
- Walking lunge with medicine ball twist
- Walkout side step lunge with resistance band around the waist
- Progress in difficulty with balancing machines
- Windmill toe touch single leg moving

Plyometrics

Plyometrics utilize the stretch reflex, muscle elasticity and the elasticity of related noncontractile structures. Plyometric training increases power and explosiveness which are required for sports. Plyometrics should be tailored to the specific sport or activities for the athlete. Considerations for initiation of plyometric training include:

- Pretraining: Age, bodyweight, strength, and experience
- Program considerations: Warmup, sport, frequency, and foot contacts
- Movements: Jumps, hops, bound, and shock
- Progression: Hops and jumps in place to standing jumps to multiple jumps or hops to depth jump to box jumps and bounding (Table 39-2)

Functional Exercises

With an Aircast or ankle lace up brace worn:

- Ladder drills
  - High knees forward
  - Side shuffle
  - Forward shuffle
  - Shuffle and stick
  - Slalom
- Agility T-Test
- 20 meter shuttle
- Hop testing
  - 6 meter for time
  - Single leg hop for distance
  - 6 meter single leg crossover hop
- Speed drill
  - First step acceleration

Table 39-2 Sample Workout for 4 Weeks (performed twice a week with 1 to 2 minute rests between sets)

	Week 1	Week 2	Week 3	Week 4
Volume	60 Foot contacts	70 Foot contacts	80 Foot contacts	90 Foot contacts
Exercises	Line hops 3×10	Line hops 2×10	Power skip 1×10	Squat jump 2×10
	Ankle Hops 1×10 side to side	Ankle Hops 2×5	Squat jump 2×10	Multiple long jumps 5×2
	Ankle Hops 1×10 front to back	Cone hops 3×5	Split Squat jump 3×5	Lateral long jump 5×1
	Cone hops 2×5	Long jump 5×1	Tuck jump 1×5	6–8 inch depth jump 5×1
	Squat jump 2×5	Split Squat Jumps2×5	Lateral long jump 1 1×10 (5 each)	Ice Skater 3×10
		Squat jumps 2×5	Box jump 2×5 front	Double leg lateral hop 2×10
			Box jump 2×5 side	

Note: Height of jumps and hops can be adjusted by size of box or cone. Length of jump can be adjusted as well. Effort should be almost maximal without pain but soreness and discomfort may be experienced. Individuals weighing 200 to 250 pounds should have their touches decreased by 25% and 250+ individuals should have their touches decreased by 50%.

Sport-Specific Exercises

With an Aircast or ankle lace up brace worn:
- Reaction drills
  - Facing partner, the partner throws the ball and once the ball goes overhead turn and retrieve
  - Facing away from the partner, the partner throws the ball and once the ball goes overhead retrieve
  - Facing wall, partner throws the ball and athlete has to react and catch (use a soft compliant ball such as a tennis ball, racquet ball, kick ball)
- Agility drills with sprint
- Partner assisted shadow drills for defense

Milestones for Progression to the Next Phase

- Y-Balance (modified SEBT) anterior reach side to side difference no greater than 6 cm and posteromedial plus posterolateral side to side difference no greater than 8 cm with minimal pain and no giving out of ankle
- Hop testing within 80% (acceptable level for return to play especially for low contact or specialist) of contralateral limb (crossover, hop for distance and 6 meter hop for time)
- Full ankle strength
- Be able to perform sports drills with little pain, discomfort and no sensation of rolling/giving out

Note: If there is a more severe injury, then progression may need to be slower. This should be based on collaboration of all members of the sports medicine team with the treating surgeon (if they are not the team physician).

If the above milestones are reached, the athlete may resume practice and/or game depending on clearance by physician and level of contact of the sport.

The younger athletes and/or less severely injured may be returning to sport by this time and will need to be progressed back into practice and training. Training with team should start out with mostly skills training and no contact for the first few sessions. If the athlete is able to tolerate these first few sessions, slowly add harder drills and light contact. Progress to full contact as the athlete is able. For the older athlete or the athlete with less than optimal fixation, the rehabilitation may need to follow the more traditional approach until fixation and healing are deemed sufficient.

Phase IV (weeks 11 to 14)

- *For syndesmosis injuries hardware removal may occur at this time and will have to allow for healing of wound for 7 to 10 days. After that can initiate rehabilitation to tolerance.*

Protection

- Continue Aircast or ankle lace up brace

Management of Pain and Swelling

- Oral analgesic as directed
- Cryotherapy as needed
- TENS as needed
- Compression and cryotherapy
- If hardware removed re-emphasize elevation

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- As needed for range of motion

Soft Tissue Techniques

- As needed for range of motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Gastrocnemius stretch and soleus stretch with slant board
- General lower extremity flexibility as needed
- Single leg gastrocnemius stretch in modified pushup position
- Single leg soleus stretch in modified push-up position

Other Therapeutic Exercises

- Progressive core activities
  - Pushups to side plank (Figure 39-31)
  - Side plank with straight lower extremity and hip abduction (Figure 39-32)
  - 45° to 90° walkouts to a pushup
  - TRX or similar device knee to chest (Figure 39-33)
  - Pushup position plank elbow to opposite knee (Figure 39-34)
  - TRX standing rotation pull from horizontal to vertical (Figure 39-35)

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Progressive activities if deficits still exist

Sensorimotor Exercises

- Continue training as previous increasing speed and decrease stability of surface two to three times a week

Open and Closed Kinetic Chain Exercises

- Progress to preinjury activities or engage in preinjury activities

Techniques to Increase Muscle Strength, Power, and Endurance

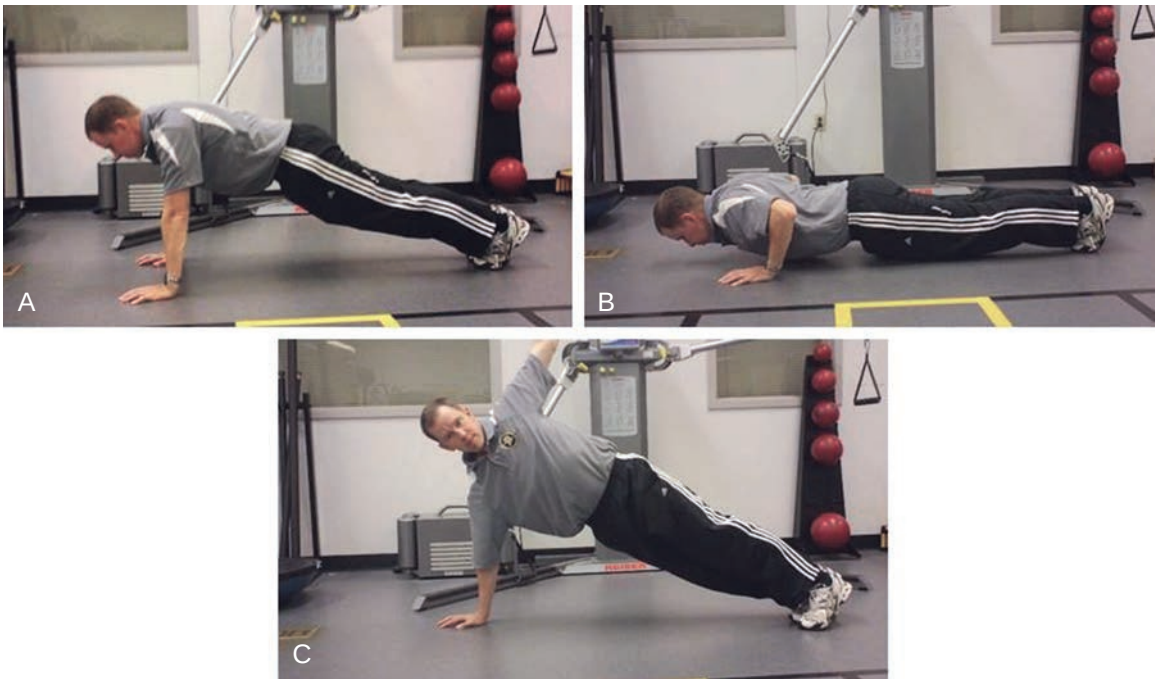
- Olympic lifts or modified
- Hybrid workouts
- Tabatas (20 second work, 10 second rest for 8 reps/4 minutes)
- Continue running fitness and progression

Neuromuscular Dynamic Stability Exercises

- Continue to progress
- Single leg activities

Plyometrics

- Multiple jumps or hops adding hurdles
- Dot drills



1. Starting position is in the push-up position (upper right)
2. Do a push-up (upper left) then come up and rotate into a side plank (bottom)
3. Alternate sides with each push-up.

FIGURE 39-31 Pushups to side plank exercise. **A,** Starting position is in the push-up position. **B,** Do a pushup. **C,** Come up and rotate into a side plank. Alternate sides with each pushup.

1. Starting in a side plank position (top)
2. Abduct upside hip and leg (bottom)

FIGURE 39-32 Side plank with straight lower extremity and hip abduction. Starting in a side plank position (**A**), abduct upside hip and leg (**B**).

1. Starting is with your feet in the handles of a TRX or similarin a push-up position
2. Alternate knees to at least waist level maintaining stability
3. Can alternate knees or bring both to waist level at the same time

FIGURE 39-33 TRX knee to chest exercise. Starting with feet in the handles of a TRX or similar device in the a push-up position (**A**), alternate knees to at least waist level maintaining stability (**B**). Can alternate knees or bring both to waist level at the same time.

1. Starting position is in a push-up position
2. While maintaining balance, bring opposite knee to opposite elbow
3. Return to push-up position and repeat with other knee and elbow

FIGURE 39-34 Pushup position plank elbow to opposite knee exercise. **A,** Starting position is in a pushup position. **B,** While maintaining balance, bring opposite knee to opposite elbow. Return to pushup position and repeat with other knee and elbow.

- Box drills
- Split Box or Bench jumps

Functional Exercises

- Sprinting drills
- More complex agility test such as Illinois agility test
- More complex ladder drills

Sport-Specific Exercises

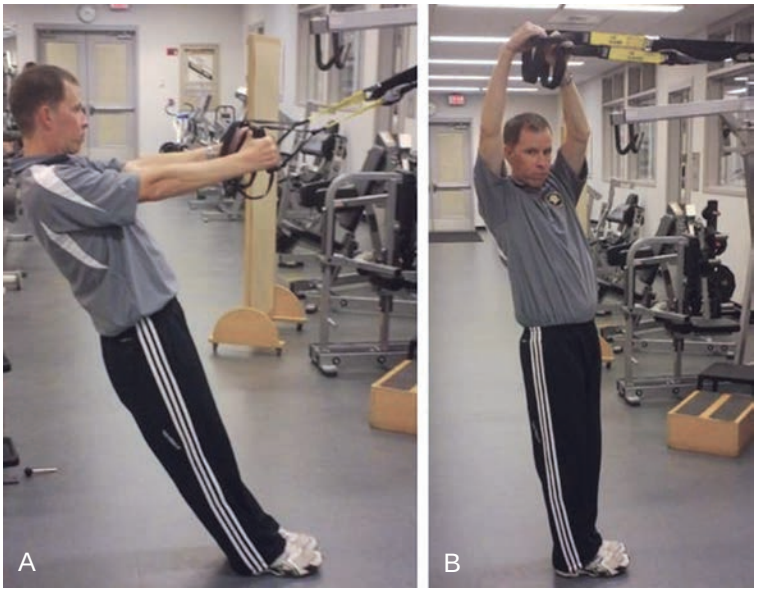
- Should be able to practice at this point

Milestones for Progression to the Next Phase

- Y-Balance (SEBT) anterior reach side to side difference less than 4 cm and posteromedial plus posterolateral side to side difference less than 6 cm.
- Hop testing within 90% (optimal level for return to sport) of contralateral limb (crossover, hop for distance and 6 meter hop for time)
- Full ankle strength
- Be able to perform sports drills with little pain, discomfort and no sensation of rolling/giving out
- At this time, most of the younger athletes will be ready to return to sport.

Phase V (weeks 15 to 24)

- Continue to rehabilitate and progress through activities/conditioning.



1. Staiting position is standing, holding TRX straps w/shoulders flexed to 90
2. Slightly leaning back to provide body-weight resistance
3. Perform trunk rotation with combined shoulder flexion motion maintaining elbows in extension

FIGURE 39-35 TRX standing rotation pull from horizontal to vertical exercise. **A,** Starting position is standing, holding TRX straps with shoulders flexed to 90°. **B,** Lean back slightly to provide bodyweight resistance. Perform trunk rotation with combined shoulder flexion motion maintaining elbows in extension.

Milestones for Progression to the Next Phase

- Return to practice/competition for older adults may occur in this timeframe. Training with team should start out with mostly skills training and no contact for the first few sessions. If the athlete is able to tolerate these first few sessions, slowly add harder drills and light contact. Progress to full contact as the athlete is able.

Criteria for Return to Sport

General

- Y-Balance (SEBT) anterior reach side to side difference no greater than 4 cm and posteromedial plus posterolateral side to side difference no greater than 6 cm.
- Hop testing (within 90% optimal, 80% acceptable for low contact and specialist) of contralateral limb (6 m single leg crossover, single leg hop for distance and 6 meter single leg hop for time)
- Full ankle strength
- Be able to perform sports drills with little pain, discomfort and no sensation of rolling/giving out
- Clearance by surgeon and/or team physician

Sport-Specific

- The above criteria
- No report of instability or giving out during specific sports drills and progressing back to practice

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Total fitness per team training or athlete's needs

Exercises and Other Techniques for Prevention of Recurrent Injury

- Single leg proprioception and dynamic stability incorporated into weekly routines

Evidence

Colvin AC, Walsh M, Koval KJ, et al: Return to sports following operatively treated ankle fractures. *Foot Ankle Int* 30:292–296, 2009.

A retrospective cohort study of 243 patients status postoperative fixation of an unstable ankle fracture investigating variables that influence return to sports. At 3, 6, and 12 months complications, weightbearing status, and function using the Short Musculoskeletal Functional Assessment and American Orthopaedic Foot and Ankle Society ankle-hindfoot scale were assessed. Males were more likely to return to sports by 3 months, younger age predictive of return to sports by 3 months, at 12 months bimalleolar injuries were more likely to return to sports than unimalleolar and patients without associated syndesmotic injury were more likely to return to sports. (Level II evidence).

Honigmann P, Goldhahn S, Rosenkranz J, et al: Aftertreatment of malleolar fractures following ORIF—functional compared to protected functional in a vacuum-stabilized orthesis: a randomized controlled trial. *Arch Orthop Trauma Surg* 127(3):195–203, 2007.

A prospective, randomized study of 45 patients with isolated malleolar fractures, comparing vacuum-stabilized orthoses with full weightbearing for 6 weeks to short-term immobilization with partial weightbearing for 6 weeks. Assessments at 6 to 10 weeks included activity limitation questionnaire, quality of life, patient satisfaction, pain, ankle dorsiflexion and plantarflexion range of motion, swelling, adverse event, return to work, and duration of hospitalization. Swelling was reduced and the ability to walk stairs confidently was shorter with the orthoses group. Otherwise, the groups were the same with no adverse events. (Level I evidence).

Hudson Z: Rehabilitation and return to play after foot and ankle injuries in athletes. *Sports Med Arthrosc* 17:203–207, 2009.

An evidence-based literature review of ankle rehabilitation in athletes. Presents the progression back to activity based on phases of healing and review of evidence. (Level II evidence).

Jelinek JA, Porter DA: Management of unstable ankle fractures and syndesmosis injuries in athletes. *Foot Ankle Clin N Am* 14:277–298, 2009.

An evidence-based literature review of management of unstable ankle fractures and syndesmosis injuries in athletes.

Presents the diagnosis, classification, treatment, and rehabilitation of the ankle fractures and syndesmosis injuries in athletes with review of evidence with regards to time to return to competition and progression of rehabilitation. (Level II evidence).

Lin CW, Moseley AM, Refshauge KM: Effects of rehabilitation after ankle fracture: a Cochrane systematic review. *Eur J Phys Rehabil Med* 45:431–441, 2009.

A systematic review of literature of rehabilitation after ankle fractures. Two reviewers using the Cochrane criterion rated prospective randomized and quasi-randomized control trials with adults undergoing any interventions for rehabilitation after ankle fracture. Activity limitation and adverse events were the main outcomes. Commencing exercises in a removable brace or splint significantly improved activity limitations but led to higher incidence of adverse events (RR 2.61) and most other interventions showed little to no effect size with activity limitations. Manual therapy showed some improvement in dorsiflexion range of motion. (Level I evidence).

Nelson AJ, Collins CL, Yard EE, et al: Ankle injuries among United States high school sports athletes, 2005–2006. *J Athl Train* 42:381–387, 2007.

A descriptive epidemiological study that investigated the incidence of ankle injury by sex, type of exposure and sport. Reviewed data collected from an injury database in Columbus, OH with specific sports studied: boys' football, boys' and girls' soccer, girls' volleyball, boys' and girls' basketball, boys' wrestling, boys' baseball, and girls' softball. Ankle injuries were significantly higher in competition versus practice and boys' sports compared to the same or similar girls' sports had higher incidence of ankle injuries. (Level III evidence).

Porter DA: Evaluation and treatment of ankle syndesmosis injuries. *Instr Course Lect* 58:575–581, 2009.

An evidence-based review of evaluation and treatment of syndesmosis injuries. Anatomy, injury classification, examination, imaging, treatment and rehabilitation were reviewed. (Level II evidence).

Porter DA, Berney T: Functional outcome after operative treatment of the ankle fractures in young athletes: A retrospective case series. *Foot Ankle Int* 29:887–893, 2008.

A retrospective case series of 27 patients investigating the functional and radiological outcomes after ORIF of distal fibula and tibia fractures with concomitant primary repair of involved ligaments ruptures in athletes. The authors compared points of interest for patients based on injury: how long crutches were used, how long the walking boot was used, how long the ankle brace was used and complications. Furthermore, return to activities of daily living, athletic practice and full competition were assessed. Athletes who undergo ORIF followed by early motion and early weightbearing were able to return to preinjury level of competition 2 to 4 months. (Level IV evidence).

Simanski CJ, Maegele MG, Lefering R, et al: Functional treatment and early weightbearing after an ankle fracture: a prospective study. *J Orthop Trauma* 20:108–114, 2006.

A prospective cohort of 43 patients investigating functional treatment with early weightbearing with matched comparison to an historical matched control (23 patients) treated with immobilization in a cast/orthoses for 6 weeks without weightbearing. Olerud (at least 12 months after surgery), Tegner (at least 12 months after surgery), time to full weightbearing, return to work, pain intensity, and hospital stay were compared. Patients with early weightbearing were full weightbearing at an average of 7 weeks (6 weeks earlier than controls) and returned to work an average of 7 weeks (3 weeks earlier than controls). Olerud scores for early weightbearing were an average of 90 out of 100 at greater than 1 year (no different than matched controls). (Level III evidence).

Stevens JE, Walter GA, Okereke E, et al: Muscle adaptations with immobilization and rehabilitation after ankle fractures. *Med Sci Sports Exerc* 36:1695–1701, 2004.

A prospective case control series of 20 subjects after ORIF of the ankle analyzing lower leg cross sectional area and torque production with 7 weeks of immobilization and subsequent 10 weeks of rehabilitation compared to matched healthy controls (six subjects). MRIs were acquired at baseline, 2 weeks and 7 weeks of immobilization to measure compartment cross-sectional area. Isometric plantar flexion strength was measured at 0, 5 and 10 weeks after immobilization. Cross-sectional area decreased the most over the first 2 weeks of immobilization and cross-sectional area increased the most over the first 5 weeks of rehabilitation. Torque output of plantar flexion increased mostly in the first 5 weeks of rehabilitation but at 10 weeks there was 20% less torque than matched controls. (Level III evidence).

Taylor DC, Tenuta JJ, Uhorchak JM, et al: Aggressive surgical treatment and early return to sports in athletes with grade III syndesmosis sprains. *Am J Sports Med* 35:1833–1838, 2007.

A prospective case series of six male collegiate athletes with grade III syndesmosis repairs. Each subject underwent internal fixation of a grade III syndesmosis injury with one 4.5 mm cortical screw. At 1 week after surgery, patients were allowed to begin range of motion exercises, progressive weightbearing, and gradually return to full activity as tolerated. Outcome measures included: return to full activity and Sports Ankle Rating System scores. Average time of return was 41 days with one screw breaking on removal and average Sports Ankle Rating System score at 34 months was 96/100. (Level IV evidence).

Vicenzino B, Branjerdporn M, Teys P, et al: Initial changes in posterior talar glide and dorsiflexion of the ankle after mobilization with movement in individuals with recurrent ankle sprain. *J Orthop Sports Phys Ther* 36:464–471, 2006.

A double-blind randomized crossover study with a control condition to evaluate the effect two mobilizations with movement (MWM) techniques in weightbearing and nonweightbearing. Sixteen subjects with recurrent ankle sprains, impaired talar posterior gliding and impaired weightbearing dorsiflexion were studied. A within-subjects study design was used to evaluate the effect of two independent variables: treatment conditions (weightbearing MWM, nonweightbearing MWM, and a no-treatment control group) and time (pretreatment and posttreatment) on the dependent variables of posterior talar glide and weightbearing dorsiflexion. Both weightbearing and nonweightbearing MWM improved talar glide over 50% versus 17% for controls and the weightbearing dorsiflexion by 26% percent versus 9% for control. MWM weightbearing and nonweightbearing help to improve talar glide and standing dorsiflexion. (Level I evidence).

Multiple-Choice Questions

QUESTION 1. The single most important factor leading to long term success for treatment of ankle fractures or instability is:

A. Anatomic reduction
B. Bone health
C. Functional rehabilitation
D. Strength

QUESTION 2. Factors that are positive predictors of return to sport after ankle fracture/instability surgery are:

A. Female gender, younger age, no systemic disease and ankle fracture only
B. Male gender, no systemic disease, ankle fracture only and surgery within 7 days
C. Female gender, no systemic disease, ankle fracture only and surgical intervention within 7 days
D. Male gender, younger age, no systemic disease and ankle fracture only

QUESTION 3. The guiding principles for safe progression of rehabilitation include all the following except:

A. Rate of healing
B. Based on the individual
C. The type of sport
D. Age

QUESTION 4. Your patient is a 19-year-old Lacrosse player status after 12 weeks an ORIF and syndesmosis stabilization to the left ankle. The fracture is well aligned and healing with the syndesmosis stabilized with a 4.5-mm cortical screw. The season is still ongoing and the player has rehabilitated well without pain or giving out during rehabilitation. What is the optimal criterion for return to sport? What additional precaution or device will you have the athlete use?

A. Y-Balance test anterior reach side to side difference <6 cm, Hop testing 80%, full ankle strength and ankle brace with no contact.
B. Y-Balance test posteromedial plus anteromedial reach side to side difference of less than 4 cm, hop testing 90%, no giving out with sports-specific activities and ankle brace.
C. Y-Balance test anterior reach side to side difference <4 cm, hop testing 80%, full ankle strength and ankle brace with no contact.
D. Y-balance test posteromedial plus posterolateral reach side to side difference <6 cm, hop testing 90%, no giving out with sports-specific activities and ankle brace.

Answer Key

QUESTION 1. Correct answer: **A**

QUESTION 2. Correct answer: **D**

QUESTION 3. Correct answer: **C**

QUESTION 4. Correct answer: **D**

POSTOPERATIVE REHABILITATION AFTER TREATMENT OF MICROFRACTURE OR CHONDRAL INJURIES OF THE ANKLE

Charles P. Hannon, BS, David Wickenden, DipPhty, MMT, FAAOMPT, Niall A. Smyth, MD, Christopher D. Murawski, BS, and John G. Kennedy, MD

Indications for Surgical Treatment

The decision to pursue surgical treatment for chondral injuries of the ankle is dependent upon multiple factors and must be individualized to each patient. After confirmation of the presence of an osteochondral lesion with magnetic resonance imaging, the general indications for surgical treatment for chondral injuries of the ankle are:

- Symptomatic patients with restriction of activities of daily living or sport activity
- Athletic patients or recreational athletes with a desire to return to sport
- Symptomatic patients with breach of the cartilaginous surface
- Symptomatic patients who fail conservative treatment after 3 to 6 months

Brief Summary of Surgical Treatment

- The most common chondral injury of the ankle joint is an osteochondral lesion of the talus. Current treatment strategies include stimulating tissue repair (i.e., bone marrow stimulation), tissue transplantation (i.e., autologous osteochondral transplantation), and cell-based techniques (i.e., autologous chondrocyte implantation, juvenile cartilage allograft).

- The most common surgical treatment for osteochondral lesions of the talus is microfracture. The major steps of this procedure are described below.

Major Surgical Steps

- Regional anesthesia with the patient placed in a supine position
- Physical exam and diagnostic arthroscopy to confirm all pathologies
- Arthroscopic debridement of frayed, soft, or fibrillated cartilage including the rim of the defect. Loose cartilage should be removed so that there is a stable edge of cartilage surrounding the defect
- Arthroscopic debridement and curettage of the osteochondral defect
- Microfracture of subchondral bone, with holes created at 3 to 4 mm intervals, ensuring there is subchondral bleeding at the defect site indicating the beginning of the formation of a fibrin clot
- Wound closure

Factors That May Affect Rehabilitation

Surgical

- Presence of other ankle pathology:
  - Osteochondral lesions of the talus are often found in conjunction with other pathologies, such as ligamentous injuries of the ankle. It is therefore important during surgery to determine if there are concomitant injuries present, as additional procedures performed may alter the postsurgical rehabilitation protocol.

Other Surgical Techniques and Options

- Major differences in other surgical techniques (if not covered in other sections)
  - While microfracture is the most common procedure for smaller, primary osteochondral lesions of the talus, other replacement strategies, such as autologous osteochondral transplantation (AOT) or autologous chondrocyte implantation, are more appropriate for larger lesions, cystic lesions and failed primary procedures. In tissue transplantation techniques, cylindrical osteochondral grafts are either harvested from the patient or from a cadaver donor, then transplanted into the prepared defect site. In cell-based strategies, a two-step procedure is required to first harvest chondrocytes, culture expand the cells *in vitro*, then surgically implant the cells.
- If these differences affect rehabilitation guidelines and, if so, how (if not covered in other sections)
  - One major difference between a microfracture procedure and AOT is that the latter requires two incisions, one at the ankle and one at the knee from where the graft is most commonly harvested. Therefore, knee rehabilitation must be added to the treatment of patients who have an AOT.

Before Surgery: Overview of Goals, Milestones, and Guidelines[2]

Patients with osteochondral lesions of the ankle commonly present with periarticular ankle pain that is exacerbated with activity and possibly associated with swelling and stiffness. The goals of preoperative rehabilitation are:

- Decrease swelling
  - Swelling is not typical with osteochondral lesions of the talus, but if present, should be managed preoperatively.
  - Cryo-compression devices are effective for managing swelling and pain.
  - Many other devices are commercially available that provide cooling and/or compression to the ankle. These devices are also commonly used in the postoperative period.
- Restoration of normal or near normal ankle range of motion.
  - Much of the exercise program preoperatively to restore normal or near normal ankle range of motion is similar to that of the postoperative period.
  - Full weightbearing and range of motion is encouraged.
  - Activities of daily living and sport activity should be conducted as tolerated.
  - Stationary cycling and elliptical machines are good exercise preoperatively to improve strength and endurance.

After Surgery-Postoperative Rehabilitation: Overview of Goals, Important Milestones and Guidelines

- Currently, there is no single standardized rehabilitation program after bone marrow stimulation for treatment of osteochondral lesions of the talus. Rehabilitation is challenging after cartilage repair procedures as there must be a balance between loading and unloading of the joint. Reduced loading of the joint with controlled motion stimulates cartilage repair, but prolonged immobilization and unloading of the joint may lead to deterioration of the cartilage. In addition, excessive loading may damage the repair tissue.
- Thus, the postsurgical rehabilitation after microfracture for treatment of chondral injuries of the ankle joint is a dynamic process that requires a team approach by the patient, orthopedic surgeon and the physical therapist. While goals and milestones are important for patients to reach towards, these are not strict guidelines that the patient must follow. Patients should allow their pain, mobility and range of motion to dictate their progression in rehabilitation. Patients should progress through their rehabilitation at a personalized and appropriate rate. Rehabilitation must be individualized

[2] *Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

to each patient and must be adaptable to change based on the condition of the patient and his or her restrictions. The aim of rehabilitation should be to return the patient to their presymptomatic activity level, whether they are recreational activities or professional sport.

GUIDING PRINCIPLES OF POSTOPERATIVE REHABILITATION

- Reduction of postoperative pain and inflammation with various modalities including cryo-compression, electrotherapy and ultrasound
- Restoration of neuromuscular control with biofeedback modalities including, but not limited to, electrical muscle stimulation and proprioceptive training
- Restoration of full ankle range of motion
- Gradual progression to full weightbearing loads on the ankle
- Sport-specific training

Phase I: Immediate Postoperative Period (days 0 to 14)

Clinical Pearls

- One of the most important aspects of the immediate postoperative period is setting expectations with the patient so they have an understanding of the extent of their pathology and realistic rehabilitation timeframes.
- It is important to stress patient responsibility with home management. The patient needs to be able to protect the cartilage surfaces and allow undisturbed healing. It should be emphasized to the patient that of the 168 hours in a week, the patient will only be spending 3 hours a week with a therapist, which, represents only a fraction of the total time. Therefore, a major role of therapy in the initial stage is to help guide the patient and educate them regarding their home and work activities of daily living, commuting and to advise what symptoms should be acceptable and what are not.

Goals

- Educate patient regarding the postoperative plan, goals, and expectations
- Instruct patient in correct use of crutches and assistive devices
- Facilitate optimal healing by decreasing acute inflammation
- Restore joint motion and passive plantarflexion
- Regain adjacent neuromusculoskeletal function and symmetry

Protection

- In the immediate postoperative period, the patient is placed in a soft dressing, often with a compression bandage.
- Patient may also be placed in an immobilization boot for up to 4 to 6 weeks while ambulating.
- Patients will be nonweightbearing up to 6 weeks postoperatively and should be instructed in the use of crutches to ambulate

Management of Pain and Swelling

- Oral analgesic medications are effective for pain. However, nonsteroidal antiinflammatories such as aspirin should be avoided as they may interfere with the natural healing response.
- Cryotherapy assists in pain inhibition and allows early active ankle movement. Cryotherapy should be applied for periods of 20 minutes with intermittent bouts of active plantarflexion. Some commercially available devices can provide intermittent compression to facilitate circulation.
- Inflammation reduction is the primary goal of the immediate postoperative period. Inflammation of the joint inhibits muscle activation.
- Elevation, compression and cryotherapy are all important for swelling reduction. Ace bandage wraps, sleeves or cryo-compression devices are commonly used. Compression cryotherapy is recommended in 20-minute intervals as needed.
- Patient should also rest the foot with elevation as much as possible. During sleep, it is recommended that the foot of the bed is elevated.
- Electrical stimulation of the musculature also improves circulation to reduce swelling.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Manual therapy to release tension in the lower leg musculature including the gastrocnemius soleus complex, plantar fascia, and tibialis anterior and posterior
- Accessory joint mobilization to mid and forefoot articulations to avoid secondary joint stiffness due to immobilization
- Gentle anterior glides and traction

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Passive stretches of the hamstring, hip flexor and piriformis to 3+/5 (moderate stretch) two to three times/day.
- Passive plantarflexion

Other Therapeutic Exercises

Core Stability
- Leg raises in the seated position

Total Arm Strength (TAS)
- Upper body activities may be completed as tolerated. It is important that all total arm strength exercises are nonweightbearing during the initial postoperative period. These exercises may include:
  - Bench Press
  - Modified chin-ups
  - Seated pulleys and free weights

Total Leg Strength (TLS)
- Open chain kinetic activities

Open and Closed Kinetic Chain Exercises

Open Kinetic Chain Exercises
- Core Stability
  - These exercises are intended to strengthen the lumbar pelvic stabilizers through four different leg exercises including hip flexion, hip abduction, hip adduction, and hip extension.
- Pilates
- Straight leg raises (hip flexion, abduction, adduction)
- Total arm strength exercises with free weights

Closed Kinetic Chain Exercises

- Nonfree weight total arm strength exercises such as bench press, seat pulley and modified chin-ups.

Milestones for Progression to the Next Phase

- Removal of sutures with a clean and closed incision
- Minimal pain and swelling of the ankle joint
- Passive ROM (plantarflexion and dorsiflexion) improving to the level needed to perform active functional movements
- Good quadriceps strength and control as demonstrated by a strong quad set and straight leg raises with no extensor lag

Phase II (weeks 2 to 6)

Clinical Pearls

- After 2 weeks postoperatively there should be an improvement in the fluidity and mechanics of the exercises from the immediate postoperative period. As this phase progresses, the difficulty of exercises may increase.
- In addition, patients often become more active in their own ADLs and they need to be educated in the signs of irritability and determine how much mechanical stimulus their joints are tolerating, become aware of how much pain is acceptable and recognize the poststimulus pain they may experience after doing a particular activity.
- Irritability is very common with ankle injuries and patients must be aware of what is too much pain. For example, patients who have pain while walking are experiencing too much pain and must rest.
- Patients can use the therapist as sounding board as to whether symptoms they are experiencing are within reasonable limits or are just too much. Everyone needs to progress at their own rate and learn to listen to how they are responding to a particular mechanical activity.

Goals

- Gradually improve functional weightbearing tolerance to full weightbearing by week 6
- Swelling and pain modulation
- Introduce ankle proprioception and dynamic stability
- Normalize accessory motion of all foot and ankle articulations
- Patient education regarding appropriate progression of activities of daily living

Protection

- After 2 weeks, the sutures should be removed and the patient should be placed in a compression bandage or sleeve to reduce inflammation

TIMELINE 39-4 Postoperative Rehabilitation after Treatment of Microfracture or Chondral Injuries of the Ankle Joint

PHASE I (weeks 1 to 2)	PHASE II (weeks 3 to 6)	PHASE III (weeks 6 to 10)
• Educate patient regarding postoperative plan, goals and expectations • Immobilization boot and instruct in proper use of crutches • Rest, ice, compression, elevation, electrotherapy • Passive • CPM ROM as tolerated • Passive hamstring, hip flexor and piriformis stretches two to three times daily • Total arm strength exercises: seated pulley • Core stabilization: straight leg raises, Pilates • Gait training with support	• Progress to nonweightbearing by wk 6 • Rest, electrotherapy, and ice as needed • Maintain full passive ankle ROM • Continue stretching program • Gradual increase in ankle ROM by stretching Achilles and soleus • Continue and progress core stability as needed • Continue and progress total arm strength exercise as needed • May start stationary bike wk 3–4 • Start elastic band exercise (all four directions) as tolerance wk 4 • Restricted balance board standing or tai chi walking by wk 4 • Quadruped, kneeling chopping wk 4 • Normal gait training with/without support as tolerance wk 3–4	• Continue stretching program • Improve ankle ROM • Total leg strength exercises: ball squat, sumo squat • Standing and calf rises in pain free range wk 8 • Nonrestricted balance board standing or tai chi wk 6 • Stationary Bike • Ankle rocking motion with resistance wk 8–10 • Introduce certain motions related to sport as tolerance • Acceptable ankle strength and endurance in full ROM • Acceptable balance for performing functional exercise

- During the 2- to 4-week postoperative period patients should remain nonweightbearing using crutches for ambulation.
- Beginning at week 4, patients may begin partial weightbearing gradually increasing 10% per day until they are full weightbearing at week 6.

Management of Pain and Swelling

- Oral analgesic medications are most effective for pain as needed. However, nonsteroidal antiinflammatories such as aspirin should be avoided as they may interfere with the natural healing response.
- Cryotherapy may also assist in pain reduction. Some commercially available devices also have compression, which is also helpful in reducing inflammation.
- Elevation, compression and cryotherapy are all important for swelling reduction. Ace wraps, sleeves or cryocompression devices are commonly used to reduce swelling. Compression cryotherapy is recommended in 20-minute intervals as needed.
- Electrical stimulation of the musculature is not as critical for this stage, but may also improve circulation to reduce swelling.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Manual therapy should work on the lower leg musculature including the gastrocnemius soleus complex, plantar fascia, and tibialis anterior and posterior to release tension in the lower leg musculature.

Soft Tissue Techniques

- Massage balls may also be used at week four at the beginning of partial weightbearing to further stretch the plantar fascia.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Continued passive stretching of the hip flexors, piriforms and hamstrings to tolerance two to three times/day.
- Begin passive stretch of the Achilles to 2+ (median moderate stretch) on a 5-stretch scale two to three times/day. Care should be taken to avoid forced dorsiflexion and compression of articular surfaces. Reduced posterior talus motion can cause hinging on the anterior articular surface due to tight posterior musculotendinous structures.
- Stretching of the anterior and posterior tibialis, gastrocnemius soleus complex, and plantar fascia with proprioceptive neuromuscular facilitation techniques.
- Begin active ankle pumps by week four. It is important to avoid forced dorsiflexion that causes any anterior mortise or talus pain.
- Stationary bike cycling may also start toward the end of week four as the patient begins gentle weightbearing.

Other Therapeutic Exercises

Core stability
- Seated leg raises
- Triathlete core exercise
  - This consists of eight exercises including a twist crunch, sky reach, marching, quadruped, lunge and twist, clap overhead, double leg raises and side bridges.
- Lunges

Total arm strength
- Upper body activities as recommended and tolerated
- Bench press
- Modified chin-ups
- Seated pulley

Free weights

TIMELINE 39-4 **Postoperative Rehabilitation after Treatment of Microfracture or Chondral Injuries of the Ankle Joint** (Continued)

PHASE IV (weeks 10 to 14)	PHASE V (weeks 14 to 24)	PHASE VI (weeks 24 to 52)
• Maintain full ankle ROM • Progressed balance board standing • Elliptical trainer • Standing chopping motions on cable • FMS routine exercise against resistance • Introduce specific sports-related exercises • Weight training: squat, deadlift • Tai chi walking • Balance board standing • Standing calf raises in full ROM • Seating calf raises in full ROM	• Maintain full ankle ROM • Single leg balance standing • Ladder drills • Dynamic lunges with resistance • Jump rope exercises • Elliptical trainers • Continued weight training • Medicine ball exercises • Jogging beginning in wk 20 • Sport-specific exercises • Bilateral jumping	• Running • Ladder drills with weights or hurdles • Boxing or mixed martial arts • Dynamic lunges • Power lifting • Sport-specific exercises • Resume full activity

Sensorimotor Exercises

- Standing, sitting to stand and weight shifting exercises
- Seated Biodex Balance System
  - The Biodex Balance System SD is a balance training biofeedback device. The user stands on a platform while viewing real-time visual biofeedback on a high-resolution color touch-screen liquid crystal display (LCD). The platform tilts 20 degrees from horizontal in all directions, and comes with two adjustable support handles that lock in place for safety or swing away for an unobstructed, open environment for a variety of training activities. The biofeedback display prompts the user into proper postural and balance control.
- Stand supported on leg and then move to unsupported and finally to dynamic movement with arm motion.
- Begin use of wobble boards (Figure 39-36), slide boards
  - Wobble boards is a semisphere or smaller spherical cap (or a shape that is approximately such) whose flat side is attached to the center of the board's underside. This allows the board to pivot in all directions during the same ride.

Open and Closed Kinetic Chain Exercises

- Open Kinetic Chain Exercises
  - Core Stability
  - Straight leg raises
  - Triathlete core exercise
  - Total arm strength exercises with free weights
- Closed Kinetic Chain Exercises
  - Stationary bike
  - Nonfree weight total arm strength exercises

Techniques to Increase Muscle Strength, Power, and Endurance

- Elastic band (TheraBand) resisted ankle motion in all four planes for endurance and strength as tolerated

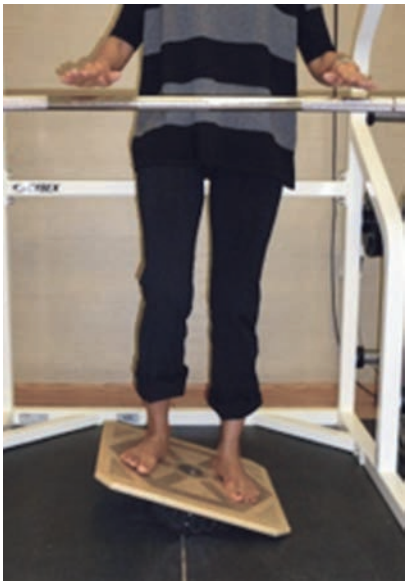

FIGURE 39-36 Wobble board balance.

- Knee extension and hamstring curl weight machines
- Pool therapy may begin with chest or shoulder-deep water walking
- Bent knee calf raises for soleus strengthening
- Calf raises with knee in extension
- Bicycling for endurance

Neuromuscular Dynamic Stability Exercises

- Kneeling chopping on cable
  - For multi-planar trunk stability. There are two ways to do it depending on ankle/knee condition: full kneeling chopping motion on cable or half kneeling chopping motion on cable.

Functional Exercises

- Walking with/without assistance to tolerance

Milestones for Progression to the Next Phase

- Full range of motion
- Acceptable ankle strength and endurance
- Acceptable balance for performing functional exercise.

Phase III (weeks 6 to 10)

Goals

- Improve static weightbearing tolerance under different loading conditions
- Improve dynamic ankle proprioception
- Improve entire lower body strength and endurance
- Enhance full pain free functional ankle and foot mobility range of motion
- Continue to monitor progression of activities of daily activities advise according to ankle irritability

Management of Pain and Swelling

- Rest, electrotherapy and ice as needed
- Ice, compression and elevation as needed

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Passive stretch soleus as well as the stretches as in Phase II

Other Therapeutic Exercises

- Core Stability
  - Straight leg raises
  - Triathlete core exercise
- Total Arm Strengthening
  - Bench press
  - Modified chin-ups
  - Seated pulley

FIGURE 39-37 Bilateral ball squat.

- Total Leg Strengthening
  - Bilateral ball squat in pain-free range of motion (Figure 39-37)
    - Squat performed on both feet when leaning on the ball for ankle isometric strength.
  - Ball squat
  - Elastic band resisted ankle motion for endurance and strength as tolerated

Sensorimotor Exercises

- Restricted balance board standing or tai chi as tolerance
- BOSU Ball Balance: Double Feet (Figure 39-38)
  - A BOSU Ball is an inflated rubber hemisphere attaching to a rigid platform. When the dome side faces up, the BOSU ball provides an unstable surface on which the patient stands
- A Biomechanical Ankle Platform System (BAPS) board is utilized to allow for anatomically appropriate motion for controlled closed chain rehab and conditioning of the lower limb. This may be utilized initially and then progressed to standing in all planes

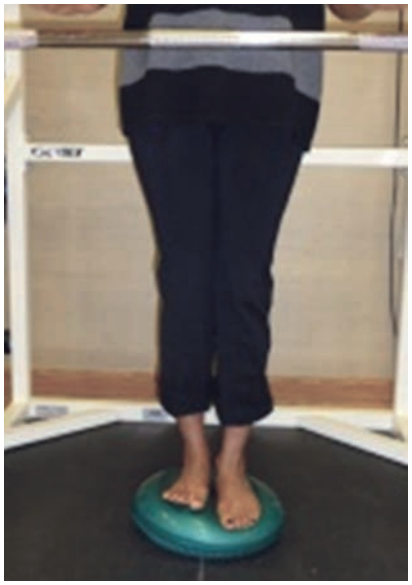

FIGURE 39-38 BOSU Ball balance: double foot.

- Progress from bilateral to unilateral and from stable ground to unstable surfaces such as foam and DynaDisc.

Open and Closed Kinetic Chain Exercises

- Open kinetic chain exercises
  - Elastic band exercises
  - Core stability
  - Straight leg raises
  - Triathlete core exercises
  - Total arm strengthening with free weights
- Closed kinetic chain exercises
  - Stationary bike
  - Ball squat
  - Seated calf raise
  - Nonfree weight total arm strengthening exercises

Techniques to Increase Muscle Strength, Power, and Endurance

- Elastic band resisted ankle motion for endurance and strength as tolerated
- Wall squats
- Standing heel raises
- Toe curls with towels
  - Rest foot on a towel and then slowly bunch up towel as the toes curl
- Step-ups

Neuromuscular Dynamic Stability Exercises

- Quadruped, kneeling chopping on cable
- Tai chi forms including walking (Figure 39-39)
- Medicine ball tossing standing on operated leg. Any shuffling and footwork drills can be used now with different catching techniques along with it to challenge the patient.

Functional Exercises

- Walking with resistance
- Ladder exercises as tolerated (Figure 39-40)

Sport-Specific Exercises

- Introduce certain motions related to sport as tolerated such as side to side jumping from one foot to the other.

Milestones for Progression to the Next Phase

- Acceptable ankle strength and endurance in full ROM
- Acceptable balance for performing functional exercise

Phase IV (weeks 10 to 14)

Goals

- Improve functional ankle stability
- Improve dynamic ankle proprioception with shared attention tasks
- Full and symmetrical lower body strength and endurance
- Optimize ankle and foot motion in all planes
- Restore confidence in performing daily activities

FIGURE 39-39 Tai chi walking.

Management of Pain and Swelling

- Rest, electrotherapy and ice as needed
- Ice, compression and elevation as needed

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Continue stretch as Phase III

Other Therapeutic Exercises

- Core stability
  - Triathlete core exercise

  Total arm strengthening
  - Bench press
  - Pushups
  - Chin ups
  - Seated pulleys
  - Free weights
- Total leg strengthening
  - Bilateral ball squat with and without weight, aiming for pain-free normal range of motion

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Elliptical trainer
- Ball squat
- Sumo squat (Figure 39-41)
  - One type of squat, which is different from front/back /deep squat in the weight loading mechanics. The overall weight loading is distributed more evenly, for example: the strength demand on back is less than back squat; the strength demands on legs are less than deep squat and front squat. Therefore, this is a

FIGURE 39-40 Ladder drills.

FIGURE 39-41 Sumo squat.

good squat for transition period from back squat to deep squat when working on leg/ankle stability.
- Standing and seated calf raises with and without weights

Sensorimotor Exercises

- Balance board standing or tai chi
- Continue to progress to unstable surfaces (BOSU ball, wobble board, Biodex Balance master) (Figure 39-42)
- Add additional challenges to exercises including writing the alphabet with the contralateral lower extremity and removing visual input

Open and Closed Kinetic Chain Exercises

- Open kinetic chain exercises
  - Core stability
  - Pilates
  - Straight leg raises
  - Triathlete core exercises
  - Upper body free weights
- Closed kinetic chain exercises
  - Elliptical trainer
  - Ball squat
  - Sumo squat
  - Seated calf raise
  - Ankle rocking against resistance (Figures 39-43)
    - There are many different ways to work ankle's dynamic stability: rocking ankle against resistance, see picture; single/double ankle rocking without resistance or even with support, see diagram.

Techniques to Increase Muscle Strength, Power, and Endurance

- Ball squat and sumo squat to tolerance
- Ankle rocking against resistance

FIGURE 39-42 BOSU Ball balance: single foot.

FIGURE 39-43 Ankle rock against resistance.

FIGURE 39-44 Standing chopping exercise on cable.

Neuromuscular Dynamic Stability Exercises

- Standing chopping on cable (Figure 39-44)
- Boxing/kickboxing or selected martial arts
- Ankle rocking against resistance

Functional Exercises

- Functional movement screening (FMS) routine exercise with/without resistance
  - Functional movement test consists of five different exercises including squat, single leg standing, in-line lunge, pushups, rotational stability.
- Begin unloaded jogging on Alter-G treadmill and progress to alternate jog/walk/jog on treadmill

Sport-Specific Exercises

- Introduce certain motions related to sport as tolerated

Milestones for Progression to the Next Phase

- Being able to perform normal daily activities
- Being able to walk at least 30 minutes without pain

Phase V (weeks 14 to 24)

Goals

- Improve ankle dynamic stability
- Improve ankle strength and endurance
- Improve ankle eccentric contraction strength
- Return to full unrestricted functional activities

Management of Pain and Swelling

- Rest, electrotherapy, and ice as needed
- Ice, compression, and elevation as needed

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Continue Stretch as per Phases III and IV

Other Therapeutic Exercises

- Core Stability
  - Triathlete core exercise

  Total arm strength
  - Bench press
  - Pushups
  - Chin-ups
  - Free weights
- Total leg strength
  - Weight lifting
  - Lunges
  - Leg press

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Elliptical trainer
- Jumping ropes
- Ball squat
- Sumo squat
- Lunge squat
- Standing and Seated calf rise with weight

Sensorimotor Exercises

- Single leg balance board standing
- Ladder drills
  - There is more ankle angles involved comparing with the normal running, one big difference is it demands more multiplanar ankle stability. The running speed, running with/without hurdles or resistance here is modified to match ankle condition.
- Tai chi

FIGURE 39-45 Jump rope: double feet.

FIGURE 39-47 Weightlifting squat.

- Continue to progress with single leg stability on unstable surfaces with exercises such as cone touches, single leg dips and lawn-mowers.

Open and Closed Kinetic Chain Exercises

- Open kinetic chain exercises
  - Core stability
  - Triathlete core exercise
  - Jumping ropes (Figures 39-45 and 39-46)
- Closed kinetic chain exercises
  - Elliptical trainer
  - Dynamic lunges and weight lifting including squats (Figure 39-47)
    - Different from static lunge. This exercise will demand more rear ankle push-off motion and more stability when the body stopped. This will be more challenging when performed with weight/resistance
  - Ankle rocking against resistance

FIGURE 39-46 Jump rope: single foot.

Techniques to Increase Muscle Strength, Power, and Endurance

- Dynamic lunge and weight lifting
- Ankle rocking against resistance

Neuromuscular Dynamic Stability Exercises

- Standing chopping on cable
- Boxing/kickboxing or mixed martial arts
- Ankle rocking against resistance

Plyometrics

- Jumping ropes
- Ladder drills

Functional Exercises

- FMS routine exercise with resistance

Sport-Specific Exercises

- Progress sport-specific exercise as tolerated

Milestones for Progression to the Next Phase

- Being able to perform bilaterally jump without pain

Phase VI (weeks 24 to 42)

Goals

- Improve ankle dynamic stability
- Improve ankle strength and endurance
- Improve ankle eccentric contractility
- Building confidence in sport-specific movement

Management of Pain and Swelling

- Rest, electrotherapy and ice as needed
- Ice, compression and elevation as needed

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Continue Stretch as in Phases III, IV and V

Other Therapeutic Exercises

- Core stability
  - Triathlete core exercise
- Total arm strength
  - Bench press
  - Pushups
  - Chin-ups
  - Free weights
- Total leg strength
  - Weight lifting
  - Leg presses
  - Lunges

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Elliptical training
- Jumping rope
- Ball squat
- Sumo squat
- Standing and seated calf raises with weights
- Lunge squat

Sensorimotor Exercises

- Single leg balance board standing
- Ladder drills
- Tai chi
- Progress with BAPS board level and add weights
- Continue progress on single leg stability with unstable surfaces (cone touches, single leg dips, lawn-mowers)

Open and Closed Kinetic Chain Exercises

- Open kinetic chain exercises
  - Core stability
  - Triathlete core exercise
  - Jumping ropes
- Closed kinetic chain exercises
  - Elliptical trainer
  - Dynamic lunges and powerlifting
  - Ankle rocking against resistance

Techniques to Increase Muscle Strength, Power, and Endurance

- Dynamic lunge and power weight lifting
- Ankle rocking against resistance
- Zig-zag cutting
- Diagonal patterns
- Figure of eights
- Back pedaling
- Carioca
  - Traditionally, carioca exercise is used for body mobility by twisting pelvis and shoulders during dynamic lateral running. Because it is carried by alternatively switching legs from anterior and posterior, the exercise will be highly dependent on the multiplanar ankle stability.
- Lateral shuffles
- Jumping progressing from bilateral to unilateral
- Trampoline Exercises (Figure 39-48)

Neuromuscular Dynamic Stability Exercises

- Standing chopping motion on cable
- Medicine ball routine for multi-plane exercise with resistance (Figure 39-49)
- Boxing/kickboxing or mixed martial arts
- Ankle rocking against resistance

FIGURE 39-48 Medicine ball exercises in multiple planes.

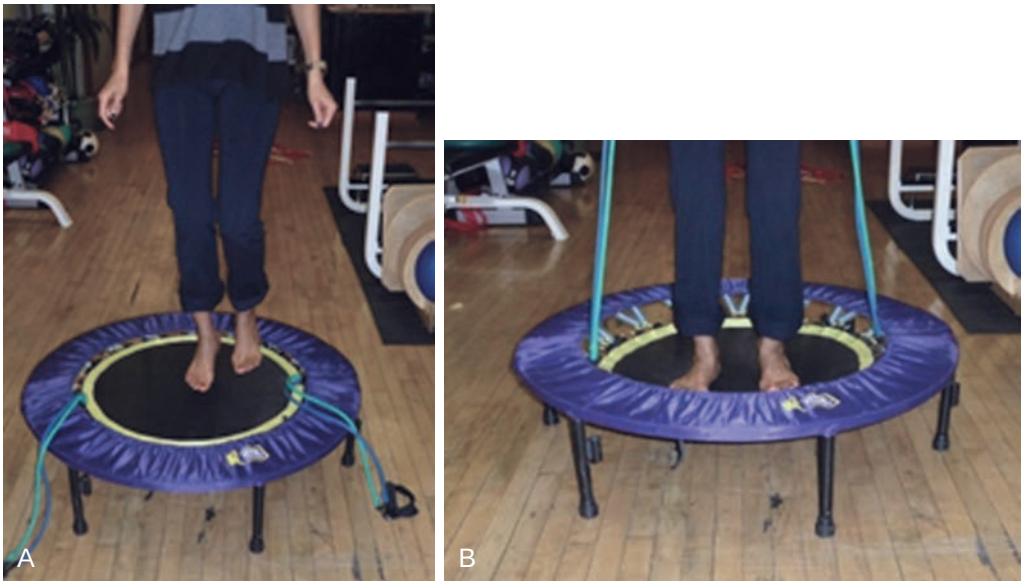

FIGURE 39-49 Trampoline exercises.

Plyometrics

- Jumping ropes
- Ladder drill with hurdles

Functional Exercises

- Progressed FMS routine

Sport-Specific Exercises

- Progressed sport-specific exercise as tolerated

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- Being able to perform single leg jump without pain

Criteria for Return to Sport

General

- Full pain-free active and passive ROM
- Able to perform any sport-specific activities without pain
- Pass FMS test
- Able to perform sport-specific movement freely
- No subjective sense of instability
- Single leg press at least 70% normal strength
- Single leg squat possible

Sport-Specific

- Long distance runner—no perceived difference between affected and unaffected ankles in endurance and stability over the appropriate distance.
- Hurdle jumper—no perceived difference between affected and unaffected ankle in strength, endurance and stability during/after hurdle race.
- Sprinter—no perceived difference between affected and unaffected ankle in perceived strength, endurance and stability during/after hurdle race during/after sprinting.

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Athletes are encouraged to continue strength and agility exercises on their own to preserve strength, function and proprioceptive gains.

Exercises and Other Techniques for Prevention of Recurrent Injury

- Lateral box jumps
- Single leg hurdles
- Cutting, accelerating and decelerating exercises
- Leg press

Evidence

Becher C, Driessen A, Hess T, et al: Microfracture for chondral defects of the talus: maintenance of early results at midterm follow-up. *Knee Surg Sports Traumatol Arthrosc* 18:656–663, 2010.

This prospective study of 45 patients evaluated the results of microfracture for treatment of chondral defects of the talus at early and midterm follow-up. The study found the HSS functional outcome and visual analogue scale improved at each follow-up time point. The study also found that all 25 ankles available for MRI follow-up at 5 years displayed some surface damage including fibrillation, fissures or ulcerations. (Level II evidence)..

Choi WJ, Choi GW, Kim JS, et al: Prognostic significance of the containment and location of osteochondral lesions of the talus: independent adverse outcomes associated with uncontained lesions of the talar shoulder. *Am J Sports Med* 41:126–133, 2013.

This retrospective cohort study compared the clinical outcomes after microfracture for osteochondral lesions of the

talus by location. The study found that in 399 patients, those patients with lesions on the talar shoulder had substantially worse outcomes than those patients with nonshoulder lesions, even when adjusting for osteochondral lesion size. The study also found that there was no difference in clinical outcomes between patients with medial and lateral osteochondral lesions. (Level III evidence).

Ferkel RD, Zanotti RM, Komenda GA, et al: Arthroscopic treatment of chronic osteochondral lesions of the talus: long-term results. *Am J Sports Med* 36:1750–1762, 2008.

This retrospective case series evaluated the clinical outcomes of 50 patients with chronic osteochondral lesions of the talus who underwent arthroscopic microdrilling. The study found that at a mean follow-up of 71 months, there was significant improvement in the average AOFAS Hindfoot score and the modified Weber scale. All patients returned to their prior level of activity, but 12% of patients needed to modify their activities. (Level IV evidence)..

Gobbi A, Francisco RA, Lubowitz JH, et al: Osteochondral lesions of the talus: randomized controlled trial comparing chondroplasty, microfracture and osteochondral autograft transplantation. *Arthroscopy* 22:1085–1092, 2006.

This prospective randomized controlled trial evaluated the clinical and radiographic outcomes after microfracture, chondroplasty and osteochondral autograft transplantation. The study found that at an average follow-up of 53 months, there was no difference in the AHS scores and SANE scores. MRI evaluation revealed incomplete fill and edema after chondroplasty and microfracture and chondral gaps evident after autologous osteochondral transplantation. (Level I evidence)..

Lee DH, Lee KB, Jung ST, et al: Comparison of early versus delayed weightbearing outcomes after microfracture for small to midsized osteochondrdal lesions of the talus. *Am J Sports Med* 40:2023–2028, 2012.

This prospective study evaluated 81 patients with single osteochondral lesion of the talus after treatment of arthroscopic microfracture treatment with half of patients placed in a delayed weightbearing group (6 weeks) and the other half in an early weightbearing group (2 weeks). The study found no differences in terms of AOFAS score, VAS score, and AAS score. (Level II evidence).

Lee KB, Bai LB, Yoon TR, et al: Second look arthroscopic findings and clinical outcomes after microfracture for osteochondral lesions of the talus. *Am J Sports Med* 37:63S, 2009.

This retrospective study evaluated second-look arthroscopies in 20 ankles at 12 months postoperative follow after microfracture for treatment of osteochondral lesions of the talus. The study found that 40% of the osteochondral lesions were incompletely healed, but 90% of ankles had excellent or good AOFAS scores greater than 80 points. (Level IV evidence).

Multiple-Choice Questions

QUESTION 1. At what time period should plyometrics begin in the rehabilitation process?

A. 1 to 2 weeks
B. 2 to 6 weeks
C. 6 to 14 weeks
D. 14 to 24 week period

QUESTION 2. Which of the following is one of the greatest differences between microfracture and autologous osteochondral transplantation?

A. The rehabilitation program for microfracture is significantly longer
B. Autologous osteochondral transplantation patients have worse outcomes after rehabilitation
C. Autologous osteochondral transplantation patients have two incisions and procedures completed and require rehabilitation of both the knee and ankle.
D. There are no differences in the rehabilitation of the two procedures.

QUESTION 3. Which of the following is not a goal of the immediate postoperative period (week one to two)?

A. Educate patient regarding postoperative plan, goals and expectations
B. Instruct patient in correct use of crutches and assistive devices
C. Restore accessory joint motion and passive range of motion
D. Restore full strength of the surrounding musculature

QUESTION 4. By what time period should the patient be able to fully weight bear?

A. Week 2
B. Week 3
C. Week 4
D. Week 6

QUESTION 5. Which of the following is not a good exercise to prevent further injury after the rehabilitation program is complete?

A. Lateral box jumps
B. Sitting leg raises
C. Leg press
D. Cutting, accelerating and decelerating exercises

Answer Key

QUESTION 1. Correct answer: **D** (see Phase V)

QUESTION 2. Correct answer: **C** (see Other Surgical Techniques and Options)

QUESTION 3. Correct answer: **D** (see Goals for immediate Postoperative Period)

QUESTION 4. Correct answer: **D** (see Phase II)

QUESTION 5. Correct answer: **B** (see Exercises and Other Techniques for Prevention of Recurrent Injury)

Chapter 40

Ankle Impingement

INTRODUCTION

Charles P. Hannon, BS, Niall A. Smyth, MD, Christopher D. Murawski, BS, and John G. Kennedy, MD, FRCS

Epidemiology

- Ankle impingement is one of the more common challenges faced by the orthopedic foot and ankle surgeon.
- Ankle impingement is a pathology defined as the entrapment of osseous and/or soft tissue overgrowth that leads to pain and decreased range of motion.
- Although the exact incidence of ankle impingement syndromes is unknown, it is commonly associated with overuse injuries and can also present with chronic ankle sprains.
- Current literature on ankle impingement is described by its location in three anatomically distinct regions: anterolateral, anteromedial, and posterior. This chapter introduces each of the three ankle impingement syndromes.

Anterior Ankle Impingement: Anteromedial and Anterolateral

- Anterior ankle impingement is a common condition seen in many athletes, particularly soccer players, dancers, gymnasts, and cross-country runners.
- Ballet dancers are prone to anterior ankle impingement with repetitive microtrauma in the forced dorsiflexion position while in the plié or demi-plié positions.
- It is also commonly found in patients who suffer recurring trauma to the anterolateral aspect of the ankle either as a result of inversion injuries or repetitive dorsiflexion.
- Anterior ankle impingement is further discussed in the literature by its location: anteromedial and anterolateral.

Posterior Ankle Impingement

- Posterior ankle impingement is a relatively common syndrome found in many athletes, particularly dancers, downhill runners, and soccer players.
- It is typically identified as a chronic injury owing to forced plantarflexion that can result in one of several pathologies.
- It may be described as os trigonum syndrome, posterior block, or talar compression syndrome.

Pathophysiology

Intrinsic Factors

- In general, any intrinsic factors that are associated with ankle sprains may predispose to ankle impingement. These include:
  - Increased body weight
  - Preexisting ankle ligament laxity
  - Ankle flexion strength asymmetry
  - Poor proprioception
  - Decreased physical conditioning
  - Younger age
  - Previous ankle sprain
- The most common form of posterior impingement is related to the os trigonum.
- The os trigonum is a congenital anomaly that forms where the talar body and lateral tubercle (Stieda process) does not fuse, and is found in 2.3% of the population.
- The presence of an os trigonum predisposes a patient to posterior ankle impingement.

Extrinsic Factors

- In general, any extrinsic factors that are associated with ankle sprains may contribute to ankle impingement. These include:
  - Increase in shoe heel height.
  - Participation in athletic activity.
  - Regarding athletic activity, participation in competitive play leads to increased risk versus noncompetitive training.

- Participation in contact sports versus non-contact sports
- Use of nonbreakaway bases in baseball and softball

Traumatic Factors

Anteromedial Ankle Impingement

- The exact cause of anteromedial ankle impingement is currently undefined, but several theories have been proposed including:
  - Repetitive capsular traction during hyperplantarflexion movements.
  - Inversion ankle sprain, including the entrapment and/or tearing of the anteromedial joint capsule and impaction between the medial malleolus and medial facet of the talus.
  - Repetitive dorsiflexion.

Anterolateral Ankle Impingement

- Commonly associated with an ankle inversion injury with concurrent damage to the lateral ligament complex.
- Recurrent instability and associated microtrauma may cause soft tissue and intra-articular hemorrhage, reactive hyperplasia, and scarring.
- Symptoms of anterolateral ankle impingement may be reproduced with compression of the abnormal anterolateral soft tissue during eversion or dorsiflexion.
- In severe cases, the soft tissue may be molded within the anterolateral recess to form a reactive hyalinized connective tissue mass termed the meniscoid lesion.

Posterior Ankle Impingement

- Posterior ankle impingement is commonly associated with repetitive traumatic injuries to the ankle.
- During plantarflexion pain is caused by either the compression of bony anomalies and/or soft tissue such as scar tissue, posterior ankle ligaments or posterior joint capsule between the posterior aspect of the distal tibia and calcaneal bone or a microenvironment of the os trigonum or an avulsion fracture fragment.
- Loose bodies or avulsion fractures of the posterior tibiotalar ligament (Cedell fracture) have been described as a cause of posterior impingement syndrome.

Classic Pathological Findings

Anteromedial Ankle Impingement

- Arthroscopic evaluation may reveal soft tissue synovial hyperplasia at the anteromedial aspect of the ankle (Figure 40-1).
- A majority of patients also have anteromedial tibial osteophytes and/or anteromedial talar osteophytes.
- In some cases, superficial fibers of the deltoid ligament may also be impinged during arthroscopic examination.

Anterolateral Ankle Impingement

- Arthroscopic evaluation demonstrates that patients may have hypertrophied, inflamed synovium that is hemorrhagic with a firm elastic consistency.

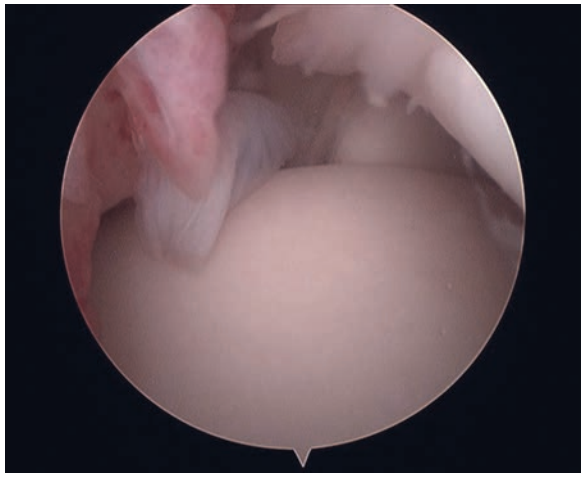

FIGURE 40-1. Soft tissue synovial hyperplasia at the anteromedial aspect of the ankle.

- Anterior tibial and/or talar osteophytes may also be evident.
- Evaluation of the cartilage may note degenerative and fibrotic changes.
- Patients may also present with adhesive bands of scar tissue similar to meniscoid lesions in the lateral gutter.

Posterior Ankle Impingement

- During arthroscopic evaluation, the patient should be placed in plantarflexion to view the impingement.
- In plantarflexion the patient may have compression of bony anomalies and/or soft tissue such as scar tissue, posterior ankle ligaments or posterior joint capsule between the posterior aspect of the distal tibia and calcaneal bone.
- An os trigonum or avulsion fractures may also be evident on arthroscopic evaluation.

Clinical Presentation

History

Anteromedial Ankle Impingement

- Patients with anteromedial ankle impingement often present with chronic ankle pain localized to the anteromedial aspect of the joint that is often exacerbated by activity or dorsiflexion motions such as running, jumping, or kicking a ball.
- Pain can typically be replicated with forced dorsiflexion of the ankle and pressing in the soft spot just medial to the anterior tibial tendon.
- Patients may also present with a history of ankle inversion injuries or ankle trauma.

Anterolateral Ankle Impingement

- Patients typically present with a history of anterolateral ankle pain and swelling exacerbated by activity.
- Patients may describe a history of ankle inversion injuries or ankle trauma.
- Patients may complain of a popping or snapping sensation in the joint during activity.

- Symptoms are often exacerbated by activity, such as running, jumping, or kicking a ball.

Posterior Ankle Impingement

- Patients with posterior ankle impingement often present with chronic ankle pain in the posterior aspect of their ankle that is exacerbated by activity, such as running or jumping, and plantarflexing the ankle.
- Patients often describe a history of a hyperplantarflexion ankle injury.

Physical Examination

Abnormal Findings: Anteromedial Ankle Impingement

- Patients often present with restricted dorsiflexion and inversion associated with soft tissue thickening of the anteromedial compartment.
- Palpation over the anteromedial ankle joint and dorsiflexing the ankle may reproduce symptoms.
- Anteromedial bony spurs may be palpable.

Abnormal Findings: Anterolateral Ankle Impingement

- Patients are typically tender upon palpation along the anterolateral aspect of the ankle.
- This pain is often reproduced at extreme passive dorsiflexion.
- A painful mass may be palpable in the region of the anterolateral gutter.
- Exacerbation of symptoms may be caused by single leg squatting and ankle eversion or dorsiflexion.

Abnormal Findings: Posterior Ankle Impingement

- Patients are typically tender upon palpation along the posterior aspect of the ankle, classically medial to the Achilles tendon.
- Patients' pain is worsened when placed in forced plantarflexion.

Pertinent Normal Findings

- When evaluating ankle impingement it is important to assess for functional and mechanical ankle stability by evaluating the integrity of the ligamentous structures of the ankle such as the anterior talofibular ligament, calcaneofibular ligament, and deltoid ligament for pathology.
- It is also important to rule out fractures of the ankle as well as any cartilage defects such as osteochondral lesions of the talus or tibia.

Imaging

- For ankle impingement both osseous and soft tissue pathology should be suspected.
- AP and lateral weight-bearing radiographs are useful images for assessing bony abnormalities such as os trigonum in posterior ankle impingement.
- Computed tomography allows for further delineation of osseous abnormalities with greater detail.
- However, to view soft tissue pathologies, magnetic resonance imaging is the most appropriate modality and should be used in all patients with suspected soft tissue impingement.
- Studies have suggested that MR arthrography has the greatest sensitivity and specificity for evaluating ankle impingement, but this is less preferred because of its invasive nature.
- Clinical association with imaging findings is essential because imaging features may also be seen without symptoms of ankle impingent.

Anteromedial Ankle Impingement

- The use of standard lateral and AP radiographs are often unremarkable when assessing anteromedial ankle impingement.
- An oblique anteromedial impingement view described by van Dijk et al. allows visualization of medial osteophytes at the talotibial articulation.
- The AMI view is an oblique 45° craniocaudal radiograph with 30° of external rotation of the leg (Figure 40-2).
- MRI should also be used to evaluate the extent of soft tissue hyperplasia, swelling, and impingement.
- It is important to obtain a MRI to also rule out any other potential medial ankle pathologies (discussed in the following).
- A diagnostic injection of local anesthetic may also be given into the anteromedial joint capsule and soft tissue. If symptoms are resolved with the injection, this is considered a positive test for anteromedial impingement.

Anterolateral Ankle Impingement

- AP and lateral weight-bearing radiographs are nonspecific for anterolateral ankle impingement, but should be obtained to rule out potential osseous causes of the patients symptoms (e.g., fracture).
- Axial T1-weighted or proton density–weighted images combined with sagittal T1-weighted images are the

FIGURE 40-2. Oblique anteromedial impingement view.

FIGURE 40-3. Prominent talar process.

most accurate for identifying soft tissue anterolateral impingement.
- MRI findings associated with anterolateral impingement include a focal mass within the gutter or hypertrophy of soft tissue and/or synovium in the lateral gutter.
- Abnormalities of the lateral ligament complex may also be visualized.

Posterior Ankle Impingement

- In patients with posterior impingement, an anteroposterior radiograph is unlikely to show abnormalities.
- Lateral radiographs may show a prominent talar process or an os trigonum (Figures 40-3). However, an os trigonum may be superimposed on the medial talar tubercle on lateral radiographs and therefore difficult to identify.
- Lateral radiographs with the foot in 25° of external rotation in relation to the standard lateral radiographs may assist in viewing an os trigonum.
- CT imaging may be useful to determine the dimension, exact location, and anatomical relationship of the os trigonum or other osseous structures present.
- MRI is also important for assessing the position of the os trigonum and the presence of any other soft tissue structures that may be causing pain.
- MRI with the foot in plantarflexion may yield additional information regarding the mobility of the os trigonum and the site of impingement.
- MRI may also show whether the os trigonum has a fibrous, fibrocartilaginous or cartilaginous attachment to the talus.

Differential Diagnosis

- There are several conditions that may cause similar symptoms to anterior and posterior ankle impingement.
- Listed in the following are several pathologies that should be included in the differential diagnosis when suspecting ankle impingement.
- A thorough history, a complete physical examination, and imaging are all important modalities to confirm the diagnosis of ankle impingement.

Anteromedial Ankle Impingement

- Osteochondral lesion of the ankle
- Stress fractures
- Injuries to deltoid ligament, spring ligament, or posterior tibial tendon
- Equinus contracture

Anterolateral Ankle Impingement

- Peroneal tendon pathology
- Sinus tarsi syndrome
- Stress fractures
- Chronic ankle instability
- ATFL, CFL pathology
- Intra-articular loose bodies
- Equinus contracture

Posterior Ankle Impingement

- Achilles tendinosis
- Flexor hallucis longus tendinosis
- Tibialis posterior tendonitis
- Deltoid ligament, posterior tibial tendon pathology
- Haglund's deformity

Treatment

Nonoperative Management

- Nonsurgical treatment for ankle impingement includes rest, cryocompression, and elevation.
- Analgesics such as nonsteroidal anti-inflammatories may also be used to reduce pain. Activities that exacerbate pain should be avoided.
- Physical therapy is also an additional nonsurgical treatment option available, to improve range of motion, proprioception, and strength.
- Physical therapy may also work to correct any motions that may contribute to the pathogenesis of the ankle impingement, such as overpronation in ballet dancers with anterior ankle impingement.
- Injections of steroids and/or local anesthetic may also be appropriate for some patients to reduce inflammation and pain.

Guidelines for Choosing Among Nonoperative Treatments

- Rest, cryocompression and elevation should be advised for all patients with ankle impingement.
- For athletes, both recreational and professional, physical therapy may be appropriate to help assist in the recovery phase and quicken the recovery time period.
- Local anesthetic and steroidal injections are intended for those patients who are limited in their activities of daily living or athletes who are unable to return to sport.

Surgical Indications

- The surgical treatment options for ankle impingement include open surgery, arthroscopy using the standard

anteromedial and anterolateral portals or hindfoot arthroscopy using posterolateral and posteromedial portals.
- The indication for surgical treatment is continued pain following 4 to 6 weeks of conservative management.

Aspects of History, Demographics, or Exam Findings that Affect Choice of Treatment

- The choice to pursue surgical treatment of ankle impingement is complex and must be individualized to each patient.
- Patients who are most appropriate for surgical treatment are those who have failed conservative management, and athletes who require a rapid return to sport.

Aspects of Clinical Decision Making When Surgery Is Indicated

- When surgery is indicated, the surgeon must decide between open surgery and arthroscopy.
- It is recommended that anterior or posterior arthroscopy be utilized for treatment of ankle impingement as it has comparative outcomes to open surgical treatment with fewer complications (e.g., infection and nerve damage).
- Of note, if a particularly large osteophyte or os trigonum needs to be removed, the arthroscopic portal may need to be enlarged or converted to open.

Evidence

Calder JD, Sexton SA, Pearce CJ: Return to training and playing after posterior ankle arthroscopy for posterior impingement in elite professional soccer. *Am J Sports Med* 38(1):120–124, 2010.

This retrospective study evaluated hindfoot arthroscopy for the treatment of posterior impingement in professional soccer players who failed nonoperative treatment. The study found that in 27 players, the average return to playing was 41 days and found that no patients had any complications at 23 months follow-up. (Level IV evidence)

Ferkel RD, Tyorkin M, Applegate GR, et al: MRI evaluation of anterolateral soft tissue impingement of the ankle. *Foot Ankle Int* 31(8):655–661, 2010.

This retrospective review evaluated the effectiveness and reliability of conventional MRI for diagnosing anterolateral soft tissue impingement of the ankle. In an evaluation of 24 patients, the study found that MRI was accurate in 78.9% of cases, with a sensitivity of 83.3% and a specificity of 78.6%. The study demonstrates that while MR arthrography has a higher specificity and sensitivity, conventional MRI is more preferred because of its less invasive nature and comparable effectiveness and reliability of diagnosing anterolateral soft tissue impingement. (Level II evidence)

Hassan AH: Treatment of anterolateral impingements of the ankle joint by arthroscopy. *Knee Surg Sports Traumatol Athrosc* 15(9):1150–1154, 2007.

This prospective study evaluated arthroscopic debridement of anterolateral soft tissue impingement in 23 patients. At an average follow-up of 25 months, the study reported an improvement in the American Orthopedic Foot And Ankle Society (AOFAS) foot and hindfoot score of 55 points with 21 patients reporting good or excellent outcomes. (Level IV evidence)

Murawski CD, Kennedy JG: Anteromedial impingement in the ankle joint: outcomes following arthroscopy. *Am J Sports Med* 38(10):2017–2124, 2010.

This retrospective study evaluated the use of arthroscopic resection for anteromedial impingement in 41 patients. The study found that at a minimum follow-up of 2 years, significant improvements in the American Orthopaedic Foot and Ankle Society (AOFAS) hindfoot and Short Form 36 outcome scores The study found that all patients, but one, returned to their prior level of athletic activity. (Level IV evidence)

van Dijk CN, de Leeuw PA, Scholten PE: Hindfoot endoscopy for posterior ankle impingement. Surgical technique. *J Bone Joint Surg Am* 91(suppl 2):287–298, 2009.

This prospective study evaluated the effectiveness, morbidity and recovery with the use of hindfoot arthroscopy for the treatment of posterior ankle impingement. The study evaluated 55 patients at a median follow-up of 36 months. The study found an improvement in the American Orthopedic Foot and Ankle Society (AOFAS) hindfoot score from 75 to 90 postoperatively as well as only one complication. (Level IV evidence)

Multiple Choice Questions

QUESTION 1. What approach should be taken remove a pathological os trigonum?

A. Open surgery
B. Ankle arthroscopy using anteromedial and anterolateral portals
C. Ankle arthroscopy using posterolateral and anterolateral portals
D. Ankle arthroscopy using posterolateral and posteromedial portals.

QUESTION 2. Which of the following imaging modalities is most sensitive and specific for diagnosing ankle impingement, but not commonly used because of its invasiveness?

A. Radiographs
B. Computed tomography
C. Magnetic resonance imaging
D. Magnetic resonance arthrography

QUESTION 3. What imaging modality provides the best view for osseous causes of anteromedial ankle impingement?

A. Anteroposterior radiograph
B. Lateral radiograph
C. 45° craniocaudal radiograph with 30° external rotation of the leg
D. None of the above

QUESTION 4. Anterior ankle impingement is most commonly found in which of these sports?

A. Soccer
B. Skiing
C. Hockey
D. Basketball

QUESTION 5. Which of the following should not be included in a differential diagnosis of posterior ankle impingement?

A. Achilles tendinosis
B. Flexor hallices longus tendinosis
C. Tibialis posterior tendinosis
D. Anterior tibialis tendinosis pathology

Answer Key

QUESTION 1. Correct answer: **D** (See Treatment)

QUESTION 2. Correct answer: **D** (see Imaging)

QUESTION 3. Correct answer: **C** (see anteromedial imaging)

QUESTION 4. Correct answer: **A** (see Anterior Ankle Impingement Etiology)

QUESTION 5. Correct answer: **D** (see Posterior Ankle Impingement Differential Diagnosis)

BEYOND BASIC REHABILITATION: RETURN TO SOCCER AFTER SURGICAL TREATMENT OF POSTERIOR ANKLE IMPINGEMENT

John Gallucci, Jr., MS, ATC, PT, DPT, Amy N. Alexander, PT, DPT, Niall A. Smyth, MD, and John G. Kennedy, MD, FRCS

ASPECTS OF SOCCER THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- The ability to sprint and jump
- Kicking the ball with the medial, dorsal, and lateral surface of the foot
- Changing sprinting direction suddenly (e.g., cutting maneuver, ability to backpedal and pivot)

Introduction

- Athletic participation in soccer subjects the ankle to a variety of acute and chronic biomechanical forces. The posterior ankle is particularly stressed because of the ankle being naturally plantar flexed in activities such as jumping, kicking, and tackling.[1] An accumulation of these biomechanical stresses or a sudden hyper-plantar flexion injury can lead to posterior ankle impingement syndrome (PAIS), a condition that has been described frequently in soccer players.[2-4]
- Treatment of PAIS is traditionally tailored around the player's season, with conservative treatment (e.g., local anesthetic and/or steroid injection) pursued initially to manage symptoms during the season.
- Definitive surgical treatment (e.g., hindfoot arthroscopy) may then be carried out in the off season.
- Unfortunately there is a direct correlation between the duration of symptoms before surgery and the postoperative time required to return to athletic participation. Therefore, a tailored rehabilitation program is important in allowing a player a quick and effective return to playing soccer.

TIMELINE 40-1: **Postsurgical Rehabilitation after Surgical Treatment of Posterior Ankle Impingement**

PHASE I (Postoperative Weeks 1 to 3)

- Communicate with MD regarding individualized postop rehab precautions specific to each case
- Ankle splint/CAM walker
- Progressive WBAT (wean from crutches)
- PT modalities for pain reduction (electrical stimulation) and edema control (cryotherapy, cold whirlpool, vasopneumatic device)
- Range of Motion:
  - AROM [plantar-flexion (pain-free to avoid compression on posterior ankle) dorsiflexion, inversion, eversion, foot circles, alphabets]
  - PROM gastrocnemius/soleus stretching in NWB position, joint mobilizations (grades 1 to 2) for dorsiflexion, inversion, eversion
- Proprioception: Biomechanical Ankle Platform System (BAPS) board seated
- Strength: ankle isometrics in pain-free range, proximal lower extremity and core musculature
- Precautions: Limit FHL activation owing to its proximity to os trigonum. Do not force plantar flexion as it will cause increased pressure on posterior ankle.

PHASE II (Postoperative Weeks 4 to 6)

- Wean from ankle splint/CAM walker, D/C crutches
- Continue PT modalities for pain reduction and edema control
- Minimize scar formation
- Range of motion:
  - AROM: Continue in all planes
  - PROM gastrocnemius/soleus stretching with increased intensity, joint mobilizations (grades 1, 2, 3) for dorsiflexion, inversion, eversion
- Proprioception: BAPS board, progress to standing in all planes
- Strength: ankle Thera-Band in all four planes (pain-free plantar flexion), standing heel raises (pain-free to avoid posterior ankle compression), toe curls with towel (avoiding FHL pain), step-ups, wall-squats,
- Balance: Progress from bilateral to unilateral and from stable (ground) to unstable (foam, Dyna-disc) surfaces

Literature

- The mean time to return to soccer following hindfoot arthroscopy for posterior ankle impingement has been described previously. In a study analyzing outcomes in 27 professional soccer players, the mean time to return to training following surgery was 34 days (range, 24 to 54 days). Mean time to return to playing was 41 days (range, 29 to 72 days).[4]

Phase I: Advanced Strength and Conditioning Programs

Periodization

- Linear

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Flexibility/joint mobility for joint stability
  - Ankle range of motion should be fully restored upon start of an advanced strength and conditioning program. The mean postoperative range of motion of the ankle joint after arthroscopic excision of posterior ankle bony impingement has been previously described and improved from 59.2° to 68.4°.[5]
  - If range of motion (ROM) is not within normal limits (WNL), the patient should perform gastrocnemius/soleus flexibility exercises and the physical therapist should perform talocrural mobilization techniques to restore ankle ROM. Early range of motion to improve integrity of soft tissue structures has been well documented in research.[6-8]
  - It is important for soccer athletes to have full ankle ROM to perform running, cutting, and stability exercises as described later in this rehabilitation program.
  - Following surgery, it is important to avoid excessive pronation as this will put increased pressure on the posterior ankle; thus it is important to teach the patient subtalar neutral position for improved foot stability.
  - Gastrocnemius and soleus stretching exercises should start in a non–weight-bearing position and should progress to a weight bearing position with increased intensity as tolerated by the athlete.
- Training with optimum posture
  - Training with optimum posture is important for patient athletes as they perform all therapeutic and functional exercises. This includes deep core muscle activation and maintaining appropriate posture throughout the entire kinetic chain.
  - As patient athletes progress in the rehab, it is important that they be taught to utilize core musculature in functional positions (i.e., activating transverse abdominis while accelerating into a sprint during soccer, this will be further expanded upon in later rehabilitation phases) (Figure 40-4).
  - Athletes are first taught to engage their core musculature in a non–weight-bearing position (i.e., performing a pelvic tilt, which is done by starting the athlete in a supine hook lying position and having him or her flatter out the back by tightening his or her abdominal muscles and pushing the pelvic bone posterior).
  - Once they have mastered this in a static, non–weight-bearing position they are progressed to a dynamic exercise in which they maintain core activation while moving their arms or legs (i.e., dead bug exercise in which the arms and legs are moving while the posterior pelvic tilt is maintained).
  - After athletes show the ability to complete this exercise without disengaging the pelvic tilt (and activation of the transverse abdominis), they are ready to perform the exercise in a functional, standing position.
  - Athletes are taught to do a squat with their back against a wall while maintaining a posterior pelvic tilt, and this concept should be translated into all therapeutic exercises that the athlete is performing (making sure to activate the core before any exercise).
  - Wall drills are also an important sport specific exercise for soccer athletes teaching them how to establish core activation in a functional position (i.e., when starting to accelerate into a sprint). They are

TIMELINE 40-1 **Postsurgical Rehabilitation after Surgical Treatment of Posterior Ankle Impingement** (Continued)

PHASE III (Postoperative Weeks 7 to 10)	PHASE IV (Postoperative Weeks 11 to 14)
• DC ankle splint/CAM walker • PT modalities as needed • ROM: full. Mobilizations as needed to maintain full ankle/foot ROM • Proprioception: Progress BAPS board level and add weight • Strength: Continue ankle Thera-Band in all four planes (pain-free plantar flexion) • Balance: Continue to progress unstable surfaces (BOSU ball, wobble board) • Biodex Balance Master if available for proprioceptive exercises. • Add perturbations, including alphabets with contralateral lower extremity, kicking/heading a soccer ball, remove visual input • Running: Begin unloaded jogging on Alter-G treadmill, progress to alternating jog/walk/jog on treadmill (no incline)	• PT modalities as needed • ROM: full. Mobilizations as needed to maintain full ankle/foot ROM • Proprioception: Progress BAPS board level and add weights • Strength: Continue ankle Thera-Band in all four planes (pain-free plantar flexion), continue proximal lower extremity strengthening • Balance Continue to progress single leg stability on unstable surfaces (lawnmowers, cone touches, single leg dips) • Running: Progress from straight jogging on treadmill to sprint/jog/sprint on flat, straight surface. Progress from running on treadmill to track to pavement to turf. • Agility drills: ladders, zig-zag cutting, diagonal patterns, figure-eights, back pedaling, carioca, lateral shuffles, jumping (progress bilateral to unilateral), plyometrics • Return to sport: Athletes return to functional return to sport with soccer-specific drills during this phase.

FIGURE 40-4. Acceleration wall drills. Place hands on a wall or soccer goal post so that the head, neck, shoulders, and hips are aligned. Start by lifting the left leg as shown. Quickly drive the left leg into the ground while lifting the right leg into position. Maintain proper posture and core stability throughout the exercise.

FIGURE 40-5. Tandem stance on a half foam roller. Athletes perform the single leg stance on a half foam roller while heading a soccer ball.

performed by having the athlete place both of his or her hands on wall or soccer goal post so that head, neck, shoulders, and hips are aligned and the core is activated. The athlete starts by lifting one leg (as shown in Figure 40-4) and then quickly drives the left leg into the ground while lifting the right leg into position. The main focus of this exercise is to maintain proper posture and core stability throughout exercise.

- Sensorimotor and balance training
  - Sensorimotor and balance exercises are progressed from bilateral to unilateral and from a stable surface to an unstable surface (i.e., foam, Dyna-discs, BOSU ball, rocker board, wobble board, dynamic Biodex balance master).
  - Figure 40-5 shows an athlete heading a soccer ball while performing tandem stance on a half foam roller.
- Core training
  - Core strengthening exercises are of upmost importance to improve stability upon return to sport and to minimize the risk of additional injury on the field.[9] Exercises should focus on activating the transverse abdominis musculature through specific training.
  - Exercises at this stage are initiated in a non–weight-bearing position (pelvic tilts, bridges with transverse abdominis activation, front planks, side planks).
  - Proximal lower extremity musculature strength should also be maintained and improved upon during rehabilitation and closed chain exercises will functionally develop strength throughout surrounding joints (i.e., progress calf press to heel raises and progress leg press to wall squats).
- Cardiorespiratory training
  - Cardio training is important to avoid deconditioning and maintain endurance with bike, arc/elliptical and Alter-G treadmill. This principle can be applied by aerobic endurance training of both fast and slow twitch muscle fibers (both of which are needed for soccer athletes).
- Multiplanar training
  - Multiplanar training activities are important because soccer athletes are constantly changing directions on the field and need to be able to quickly plant their feet and cut. Multiplanar training activities include progressions on BAPS board (non–weight-bearing to weight-bearing position) and plantar/dorsiflexion, inversion/eversion, and clockwise/counterclockwise movements.
  - Strengthening exercises should challenge musculature both concentrically and eccentrically. Isotonic strengthening includes Thera-Band exercises (all planes throughout full ROM) and manual, progressive resistance exercises.
- Training for optimum muscle balance
  - Balance exercises are progressed from bilateral to unilateral and from firm surfaces to unstable surfaces. Additional perturbations are added (soccer kicks while performing single leg stance on opposite leg for soccer players) and taking away visual input are appropriate advancements.
  - Athletes should be able to display appropriate single leg stability before advancing to functional soccer drills. This is determined by having the athlete stand on one leg. He or she should be able to balance on an uneven surface (foam, Dyna-disc, BOSU ball) for at least 30 seconds without loss of balance before starting any sports specific single leg balance exercises.

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of variation

- Principle of individualization
- Principles of specificity: specific adaptation to imposed demands (SAID)

Application of Acute Training Variables

- Acute training variables vary based on the athlete's preoperative condition, training background, and exercise history. These variables, listed in the following, affect how the body adapts to resistance exercise.[10]
  - Repetitions: 8 to 10 repetitions of each exercise
  - Sets: two to three sets of each exercise
  - Rest interval: 60 seconds between sets
  - Intensity: Dependent upon the specific goals of the athlete; however should be low intensity at this point in the rehabilitation. Athletes should begin with a low weight and progress to a heavier weight once proper form is established. The exercise should be challenging by the third set of 8 to 10 repetitions.
  - Repetition tempo is dependent upon the goal of the athlete. At this point in the rehabilitation, patient athletes are most likely looking to gain maximal strength, so a slow, eccentric contraction is best.
  - Training frequency two to three times per week
  - Training duration should be about 30 to 60 minutes for each workout and is dependent upon the athlete and his or her specific glycogen stores.
  - Training volume is dependent upon the other acute training variables as described in the preceding.

Phase II: Performance Enhancement Training Techniques

Periodization

- Mesocycles

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Flexibility/joint mobility for joint stability
  - Patients should have full ankle ROM before performance enhancement training techniques. It is important to maintain a stretching routine for gastrocnemius and soleus musculature along with hamstring, psoas, piriformis, and TFL for soccer athletes because they need to be agile on the field and to decrease risk of further injury.[11]
- Training with optimum posture
  - As in previous stages of rehabilitation, it is important to continue to maintain optimum posture throughout rehabilitation and when transitioning to soccer specific drills because it is essential to have a sturdy base of support from which to accelerate off.
- Sensorimotor and balance training/training for optimum muscle balance
  - Sensorimotor and balance exercises should focus on unilateral stance on an unstable surfaces (i.e., foam, Dyna-discs, BOSU ball, rocker board, wobble board, dynamic Biodex balance master) at this point in the rehabilitation.

FIGURE 40-6. Single leg stance on BOSU with a soccer kick. Athletes perform a single leg stance while kicking a soccer ball with the opposite leg.

  - Further progressions in proprioception include removing visual support, adding perturbations, kicking a soccer ball with the opposite lower extremity (Figure 40-6), or heading a soccer ball while maintaining balance.
- Core training
  - Core training exercises should progress from non–weight-bearing positions to functional weight-bearing positions. Wall drills (see Figure 40-4) teach core musculature activation in soccer specific positions.
  - Athletes should also focus on core activation during sudden changes of position and landing from a jump.
- Cardiorespiratory training
  - Patient athletes should maintain an appropriate cardiovascular endurance level on the bicycle so that when they are ready to return to sport specific drills they are not deconditioned and do not become easily fatigued; thus mitigating the risk of further injury.
  - Patient athletes progress to a running program once cleared by treating physician. This determination is specific to each treating medical doctor; however usually it is determined based on the patient's subjective reports, results of objective tests/measures by the MD (full ROM, 5/5 strength, single leg stability without loss of balance, single hop test), and the level of play of the athlete.
  - The running program starts on an Alter-G treadmill with a percentage of body weight unloaded, progressing to alternating jog/walk/jog on treadmill and then to straight running.
- Multiplanar training activities
  - Multiplanar training activities should be progressed at this point in the rehabilitation from non–weight-bearing exercises (ankle four-way progressive resistive exercises) to weight-bearing exercises (multidirectional lunges and multidirectional heel raises), which further improve strength and endurance of ankle musculature.

- Training for optimum muscle functional strength
  - At the beginning of this phase patient athletes should demonstrate the ability to perform bilateral heel raises without pain or apprehension, especially with going into plantarflexion because this may exacerbate the surgical site.
  - The patients then progress into the ability to perform unilateral heel raises before advancement to sport-specific soccer drills.
- Training for optimum muscle functional power
  - To train for optimum muscle function power, patients should vary acute training variables. Once patients are able to perform the exercise with proper form at low intensity, they may be progressed to short bouts of higher intensity work.

Phase III: Sport-Specific Training

Periodization

- Macrocycles
- Mesocycles

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Flexibility/joint mobility for joint stability
  - Athletes should have full ROM and flexibility at this stage in sport specific training. It is important to maintain flexibility for appropriate muscle balance.
- Training with optimum posture/sensorimotor and balance training/core training
  - It is important to maintain training with optimum posture including core stability training and balance training as previously described.
- Cardiorespiratory training
  - Athletes should continue to maintain a base level of endurance through a running program. The running program for each athlete is specific to their cardiovascular endurance and the position they play/level of endurance they need to maintain. There is no one specific running program for every athlete, it should be a tailored program developed by the medical professional treating that particular athlete.
  - Soccer-specific field conditioning should be implemented at this phase which can include ball touches and dribbling within a 10 × 10 yard box starting at 30-second intervals and progressing to 20 × 20 yard box at 60-second intervals as endurance and conditioning goals are met.
- Multiplanar training activities
  - Athletes should continue to progress their multiplanar training activities as it relates to soccer specific movements. Resistance via sport cord with multidirectional lunges and adding intensity to lateral drills are both functional exercises for the soccer athlete.
- Training for optimum muscle balance/neuromuscular dynamic stability exercises
  - Balance exercises should focus on unilateral stability on unstable surfaces. Additional perturbations should be added in order to continuously challenge the athlete (e.g., soccer kicks while performing single leg stance on opposite leg) and taking away visual input are appropriate advancements.
- Training for speed, agility, quickness (SAQ)
  - Speed, agility, and quickness training involves sprints, speed ladder drills, and acceleration drills. Ladder drills are performed in various challenging patterns (Figure 40-7) that simulate movements an athlete performs on the soccer field.
  - Adding in a quick soccer kick or dribbling at the end of each set of the ladder drill adds an additional functional component for the athlete. Speed, agility, and quickness circuits should be progressed from forward drills to lateral (Figure 40-8), backward, and randomized movements.
- Plyometric training
  - Plyometric drills utilizing explosive, fast-twitch movements are important for soccer players to develop power and speed as needed on the field to be faster and stronger than their opponents.
  - Plyometric drills should begin bilateral, are progressed to unilateral, and include: hopping over a soccer ball on one foot, bounding, box/depth jumps (Figure 40-9), lateral jumps (Figure 40-10), hurdle hoping.
  - Athletes rehabbing from ankle surgery should take into consideration the rigidity of surface on which they are performing plyometric drills. Performing such drills on softer surfaces such as a track or a grass field will reduce unnecessary stress on joints.
- Functional/sport-specific training
  - Many of the drills described in the preceding entail a significant amount of soccer specific training. Adding soccer kicks and heading a soccer ball into

FIGURE 40-7. Agility ladders. Athletes can perform ladder exercises various ways (both vertical and horizontal to challenge the ankle musculature). Types of ladder drills include quick-step, three forward/one back, high knees, in-in-out-out, and dance step. Athletes should kick a soccer ball at the end of the ladder as a progression into sport-specific training.

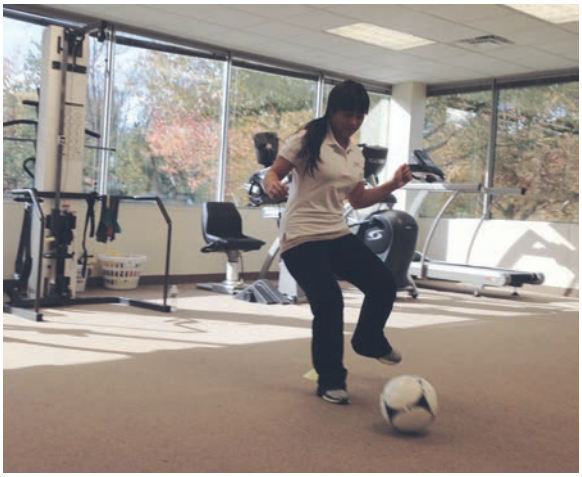

FIGURE 40-8. Lateral shuffles with a soccer kick. Two cones are set up about 40 feet apart. Athletes start in an athletic stance and perform a lateral shuffle to the left, a soccer ball is tossed to them, and they must kick the ball while quickly changing directions. Repeat, going in the other direction.

FIGURE 40-9. Box jump. Start with the feet shoulder width apart. Bend the hips and knees and jump with both feet landing on the box. (The knees should be bent on landing.) This movement should be explosive.

FIGURE 40-10. Bilateral lateral jump. Start in an athletic stance, jump with both feet laterally over a line and back for one repetition. Be sure to land with the knees bent.

the balance and plyometric exercises add an additional sport-specific component for the athlete.

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload
- Principle of variation
- Principle of individualization
- Principles of specificity: specific adaptation to imposed demands (SAID)

Application of Acute Training Variables

- Repetitions: 8 to 10 repetitions of each exercise (should be challenging to complete the third set; however the athlete should maintain proper form with each exercise)
- Sets: three sets of each exercise
- Rest interval: 30 to 60 seconds between sets
- Intensity: Dependent upon the specific goals of the athlete; however, intensity should be high at this point in the rehabilitation. The exercise should be challenging by the third set of 8 to 10 repetitions.
- Repetition tempo is dependent upon the goal of the athlete. For those who are looking to gain maximal strength, a slow, eccentric contraction is best. Faster tempos are better for soccer athletes looking to improve power and explosive strength. This is also dependent upon sport season.
- Training frequency three to five times per week (for specific return to soccer drills)
- Training duration should be about 30 to 60 minutes for each workout and is dependent upon the athlete and his or her specific glycogen stores.
- Training volume is dependent upon the other acute training variables as described above.

Application of Chronic Training Variables

- Chronic training variables are dependent upon the sport season for the specific athlete. Soccer athletes in the off-season will perform high level resistance training to improve muscle endurance, strength, and power.
- During the preseason, equal priority is given to sport specific training and strength training.
- Athletes that are in season focus on maintenance of strength, whereas practice time focuses on sport-specific movements and functional drills.
- During the post-season, athletes focus on maintaining muscle endurance and sport-specific skills while actively resting.

Sports Performance Testing

General Information

- General history
- Subjective questionnaires
- Medical history
- Sports injury history
- Surgical history
- Chronic conditions/medication
- Pain level

Objective Tests

- Physiological assessments: pulse measurement (resting and post workout), respiration measurement, body temperature, blood pressure, pulse oximetry, peak flow, weight, height, VO_2max
- Orthopedic assessments: ROM, strength
- Body composition tests
  - Body fat composition
  - Flexibility: sit and reach test
- Static/dynamic postural assessments
  - Static: plumb line
  - Dynamic: Assess athletes gait pattern while running, jumping, kicking, sprinting, and cutting. Gait analysis can be performed by a trained healthcare professional who looks at step length, stride length, cadence, speed, hip/foot/knee angle, pelvic rotation, amount of foot pronation, arm swing, and base of support at various angles. Gait labs can give a more objective measure of a patient's gait by placing markers on various bony landmarks on the body and then having the athlete walk on the treadmill and/or perform sport-specific activities while taking video. Computer-software and force-plates then give a breakdown of the movement of each joint.
- Movement performance testing
- Functional movement screen (deep squat, hurdle step, in-line lunge, active straight leg raise, trunk stability pushup).
- Minimal research is documented on elite soccer players and the Functional Movement Screen to determine injury risk. Chorba et al.[12] looked at 38 NCAA Division II female athletes (soccer, volleyball, and basketball) ad found a score of 14 or less on the FMS tool resulted in a fourfold increase in the risk of low extremity injury.
- Sport-specific testing
  - 40 yard dash
  - Vertical jump
  - Broad jump
  - Sprint repeats
  - Shuttle run

Specific Criteria for Progression to the Next Stage to Determine Readiness for Soccer

- Progression of an athlete from one stage to the next is a multidimensional decision involving a team of healthcare providers.
- An athlete should be able to complete all treatment goals in the previous phase before progression to the next phase (i.e., patient athletes in an early strengthening phase should display normal ROM/flexibility, sufficient strength base, and equal balance of affected vs. unaffected lower extremity before advancement to sport-specific training).
- Patient athletes need to be able to run pain-free and have 5/5 manual muscle testing (MMT) strength throughout their lower extremity (including the ankle) to begin the sport specific training.
- The Foot and Ankle Ability Measure (FAAM) is a reliable measure of performance during ADLs and

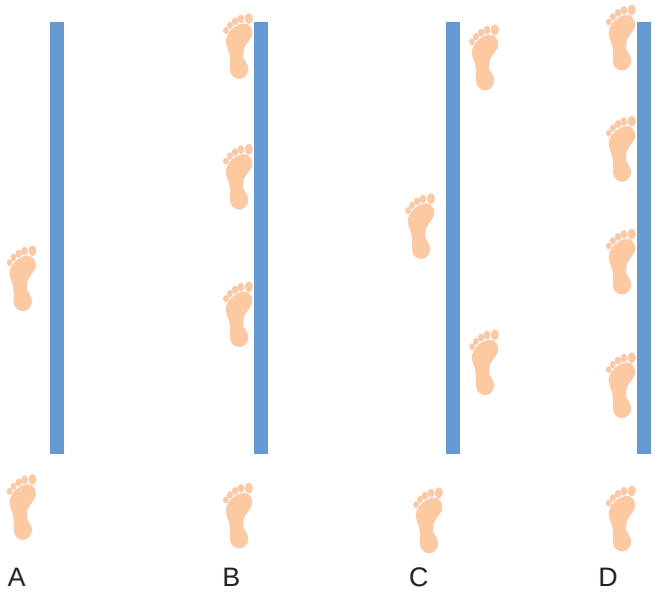

FIGURE 40-11. The single leg hop test. The athlete performs (1) a single leg hop for distance, (2) a triple straight hop for distance, (3) a triple cross-over hop for distance, and (4) a 6-meter timed hop. The athlete should be able to perform the test at 85% of the unaffected extremity before returning to sport.

sport-specific activities for individuals affected by an ankle injury. Physical performance of function can be measured with the four-part single leg hop test (also referred to as the Limb Symmetry Index when compared with the unaffected side, athletes should be able to perform the hop test at greater than 85% on affected limb vs. unaffected limb, as long as no other injury has been sustained on the opposite limb). The athlete performs: (1) a single leg hop for distance; (2) a triple straight hop for distance; (3) a triple crossover hop for distance; and (4) a 6-meter timed hop. The athlete should be able to perform the test at 85% of the unaffected extremity before returning to sport (Figure 40-11).

- The Single Leg Hop Test has been proved to be a convenient, reliable, and valid outcome measure during rehabilitation.[13] It is important to look at functional movements and perform a biomechanical video analysis of sport specific activities.

Specific Criteria for Release to Unsupervised Complete Participation in Soccer

- The length of time for a patient to return to full sport is dependent on many factors, including physical fitness and level of sport play.
- It is recommended that a patient demonstrate 85% strength in affected versus unaffected lower extremity. This is measured by the single leg hop test (as in the preceding).
- Patients should demonstrate ability to carry out functional sport specific testing (running, cutting, jumping, sprinting, kicking a ball) before clearance.
- The Drop Vertical Jump Test has been repeatedly shown in the literature to identify lower extremity biomechanics during plyometric activity.[14] The test is performed by having the athlete do a double-leg jump landing from a 31-cm step and then immediately perform a maximum effort double-leg jump. The athlete is evaluated by visually (or by video analysis) observation: symmetry of both feet leaving the box, feet landing simultaneously, and symmetry of weight bearing. This tests for mechanical faults or neuromuscular control deficits that can be worked on with therapeutic exercises if found.
- The Tuck Jump assessment (Figure 40-12) also has been found reliable in identifying landing techniques in plyometric athletic activity.[15] The athlete performs repeated tuck jumps for 10 seconds while the clinician visually assesses form. (Video analysis may be used for accuracy.) If a patient demonstrates six or more flawed techniques, further therapeutic exercises to address deficits before clearance for sport would be beneficial.[16]
- Athletes should be progressed into sport by returning first to practice at 50% intensity and then progressing by 25% intensity each week.
- Practice situations should start as noncontact, progress into three versus three small-sided games, then to five versus five games, and finally, progress to full contact.
- Lack of apprehension with sport-specific drills is also imperative before return to sport. This is tested by using the FAAM (as in the preceding) along with the Single Leg Hop Test, Drop Vertical Jump Test, and Tuck Jump Assessment (all as in the preceding).
- Patients must have clearance from referring/surgical physician before returning to soccer.

Recommended Ongoing Exercises

- Athletes often target large muscle groups while participating in a sport (especially while in season); however atrophy may occur in smaller muscle groups when training focuses on sport-specific drills and not on strength training.
- It is recommended that athletes continue to focus on balance and proprioceptive exercises throughout their participation in soccer along with stability muscle exercises targeting the peroneals and intrinsic muscles of the foot.
- Maintenance of core muscle strength is imperative in soccer players as well.

Evidence

Calder JD, Sexton SA, Pearce CJ: Return to training and playing after posterior ankle arthroscopy for posterior impingement in elite professional soccer. *Am J Sports Med* 38(1):120–124, 2010.

Case series of 28 professional soccer players who underwent arthroscopy for posterior ankle impingement. The mean length of time to return to training was 34 days (range, 24 to 54 days), and mean length of time to return to playing was 41 days (range, 29 to 72 days). All players were competing symptom free at an average follow-up of 23 months. (Level IV evidence)

Willson J, Dougherty C, Ireland M, et al: Core stability and its relationship to lower extremity function and injury. *J Am Acad Orthop Surg* 13:316–325, 2005.

Core stability is predominantly maintained through dynamic function of muscular elements. Current evidence indicates

Tuck Jump Assessment	Pre	Mid	Post	Comments
Knee and Thigh Motion

	Total _____	Total _____	Total _____	

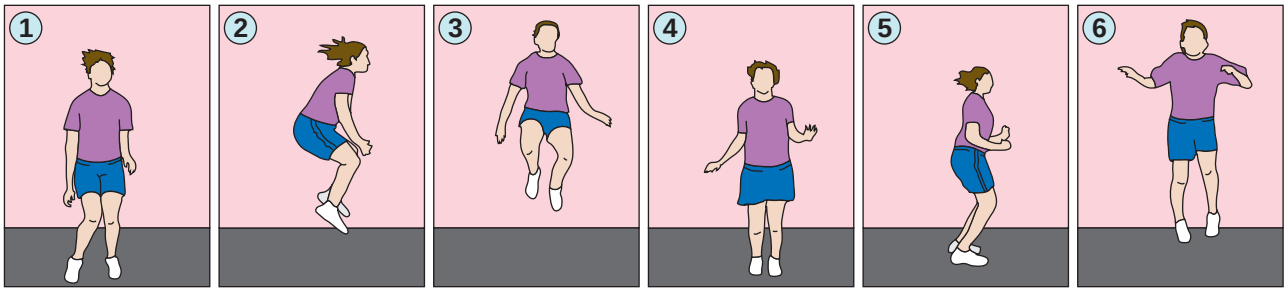

FIGURE 40-12. The tuck jump assessment. The athlete performs repeated tuck jumps for 10 seconds while the clinician visually assesses his or her form. If six or more flawed techniques are observed, further therapeutic exercises to address deficits before clearance for sport would be beneficial: (1) unwanted medial knee collapse; (2) knees not parallel at the top of flight; (3) lower limb positions not synchronized during flight; (4) landing with feet too close together; (5) landing in a staggered position; and (6) not landing with both feet at the same time. *(Redrawn from Myer GD, Ford KR, Hewett TE: Tuck jump assessment for reducing anterior cruciate ligament risk. Athl Ther Today September:39–44, 2008.)*

that decreased core stability predisposes to injury, particularly lower extremity injury. Core stability is tested and improved through isokinetic, isometric, and isoinertial exercises.

Witvrouw E, Danneels L, Asselman P, et al: Muscle flexibility as a risk factor for developing muscle injuries in male professional soccer players. *Am J Sports Med* 31(1):41–46, 2003.

One hundred forty-six professional soccer players with no previous history of injury had the flexibility of their hamstring, quadriceps, adductor, and calf muscles measured goniometrically, and injuries to these muscle groups were recorded. The authors concluded that over the course of a full soccer season, players with increased tightness of the hamstring or quadriceps muscles have a statistically significant increase in risk of developing an injury. (Level II evidence)

Multiple Choice Questions

QUESTION 1. If postoperative range of motion of the ankle is not within normal limits, which muscle group should be worked on with flexibility exercises?

A. Tibialis anterior, extensor digitorum
B. Peroneus longus, peroneus brevis
C. Tibialis posterior, flexor hallucis, flexor digitorum
D. Gastrocnemius, soleus

QUESTION 2. When training for optimum muscle balance, what are appropriate progressions that may be added to the exercises for the athlete to advance?

A. Removing auditory signals
B. Removing visual input
C. Progressing from unilateral stance to bilateral stance
D. Progressing from unstable surface to stable surface

QUESTION 3. Following surgery, which ankle motion should be most cautiously advanced because it may irritate the surgical site?

A. Dorsiflexion
B. Plantarflexion
C. Inversion
D. Eversion

QUESTION 4. Once the patient athlete has started sport-specific training, how should his cardiorespiratory training progress?

A. Ball touches and dribbling exercises within a 10 × 10 yard box
B. Full soccer pitch sprints
C. Stair climbs
D. Long distance track running

QUESTION 5. What criteria should be used in order to release the athlete into athletic activity without supervision?

A. Strength at 50% of contralateral leg
B. Able to single heel raise on the postsurgical side
C. Strength at 85% of contralateral leg
D. Patient is able to plantarflex on the postsurgical side without pain

Answer Key

QUESTION 1. Correct answer: **D** (see Phase I)

QUESTION 2. Correct answer: **B** (see Phase I)

QUESTION 3. Correct answer: **B** (see Phase II)

QUESTION 4. Correct answer: **A** (see Phase III)

QUESTION 5. Correct answer: **C** (see Specific Criteria for Release to Unsupervised Complete Participation in Soccer)

Chapter 41

Flexor Hallucis Longus Tendinopathy

INTRODUCTION

William G. Hamilton, MD, BSE, AAOS, AOA, FACS, Marika Molnar, PT, LAc, and Nadia Sefcovic, DPT, COMT

Epidemiology

Flexor hallucis longus (FHL) tendinopathy (dancer's tendinitis) is common in female ballet dancers who perform in toe shoes. It is rare in athletes.

- Age: early teens to early 40s
- Sex: females (male dancers rarely dance in toe shoes)
- Sport/Art: usually ballet, but occasionally in other dancers and athletes
- Position: maximum plantarflexion

Pathophysiology

Intrinsic Factors

- The FHL tendon is the "Achilles tendon of the foot" for the ballet dancer working on pointe.
- The tendon has its origin on the posterior fibula, crosses behind the ankle and passes through a fibroosseous tunnel on the medial side os calcis then exits into the arch of the foot.
- It can become strained and swollen within this tunnel, setting up a repetitive cycle: because it is swollen, it binds as it moves and the binding, in turn, causes swelling and irritation, etc.
- If the condition is chronic, the tendon can develop a fibrous knot that causes triggering of the great toe ("hallux saltans") (Figure 41-1).
- Splits and partial tears can develop in the tendon but these are infrequent (Figure 41-2).
- FHL tendinitis can be associated with *posterior impingement* on an os trigonum or trigonal process ("Stieda's process") (Figure 41-3).
- At times, the differentiation between these two syndromes can be difficult, because they can exist separately or together.
- Posterior impingement does not cause FHL tendinitis. They are two separate syndromes that may coexist.

FIGURE 41-1. A nodule on the FHL tendon causing triggering of the hallux.

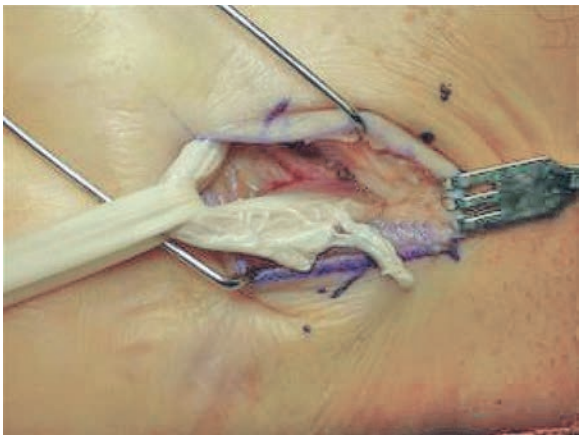

FIGURE 41-2. A serious tear of the FHL with shredding of the tendon.

FIGURE 41-3. Posterior impingement on an os trigonum.

Extrinsic Factors

- Toe shoes and pointe work contribute to the injury, although it can be found in male ballet dancers and even modern dancers who usually dance barefooted.
- It is a common "overuse" injury in this group of performers.
- It is rare in athletes but can occasionally be seen in pronated runners along with the "jogger's foot" (tendonitis at Henry's knot).
- It can occur in athletes such as place kickers in American football.
- The author has removed the os trigonum of a place kicker of an NFL professional football team.
- Hard floors, fatigue, and poor technique ("rolling in," or pronating) can contribute to this injury.
- It is frequently misdiagnosed as posterior tibial tendinitis, which is relatively common in athletes but rare in dancers.

Traumatic Factors

- This is rarely an acute injury. It is almost always caused by overuse.
- Forced plantarflexion in the presence of an *os trigonum* or *trigonal process* is usually the cause of posterior impingement.
- Posterior impingement can be associated with fractures of the posterior process ("Shepherd's fracture") (Figure 41-4).

Classic Pathological Findings

- FHL tendonosis results in chronic swelling and inflammation in the tendon as it enters or passes through the fibroosseous tunnel on the medial side of the os calcis.
- The swelling can cause ganglion-like cystic formation behind the ankle.

FIGURE 41-4. Fracture of the posterior process—"Shepherd's fracture."

- Posterior impingement causes inflammation, fractures, cystic changes, and occasionally displacement of the os trigonum (Figure 41-5).

Clinical Presentation

History

- The pain is usually activity related and relieved by rest.
- FHL tendonitis presents as posterior *medial* ankle pain without a history of trauma.
- Posterior impingement usually causes posterior *lateral* pain and may have a definite onset. It is exacerbated by plantarflexion such as pushoff in running and relevé in ballet (going up in a toe raise).
- The symptoms are frequently mistaken for strains of the Achilles or posterior tibial tendons.

Physical Examination

Abnormal Findings

- Localized pain and swelling behind the ankle over the FHL tunnel medially or over the os trigonum posterior laterally, or both
- Increased pain with plantarflexion, especially when forced—the positive "plantarflexion sign." It is only

FIGURE 41-5. Displacement of the os trigonum when the ankle is plantarflexed.

FIGURE 41-6. The "plantarflexion sign" for posterior impingement.

positive for posterior impingement, not for FHL tendonitis. This sign differentiates posterior impingement from all other causes of posterior ankle pain (Figure 41-6).
- Pain in FHL tunnel with active and passive motion of the first MP joint
- Triggering of the Hallux may be present.
- Tenderness over the FHL tunnel behind and below the medial malleolus
- Range of motion of the ankle may be reduced because of pain.

Pertinent Normal Findings

- No ecchymosis
- No effusion within the ankle joint
- No pain with dorsiflexion
- No loss of subtalar motion
- The "drawer sign" for ankle ligament will be negative.
- There is usually no peroneal tendon weakness.
- Examination of the posterior tibial tendon and Achilles tendon is normal.

Imaging

- Lateral radiographs taken in foot flat and in forced plantarflexion on in full toe raise will help diagnose posterior impingement but will not show FHL tendonitis.
- Sonography will reveal swelling of the FHL tendon.
- An MRI study will show the swollen FHL tendon and fluid within the sheath and tunnel surrounding it. This fluid may extend upward to the posterior ankle area and can be mistaken for joint fluid (Figure 41-7).
- Imaging studies do not always pick up tears, partial tear, and rents in the tendon.
- Often a sonogram will show these better than an MRI.
- A bone scan will be negative for FHL tendonitis but positive for posterior impingement.

Differential Diagnosis

- An osteochondritis dissecans lesion of the posterior talar dome
- Early arthritis or degeneration of the posterior facet of the subtalar joint
- A fibrous middle facet tarsal coalition
- Posterior tibial or Achilles tendinitis or strain

Treatment

Nonoperative Management

- Relative rest—"don't do what hurts" and antiinflammatory medications
- Physical therapy modalities such as phonophoresis, iontophoresis, and acupuncture
- Technique correction if this is a contributing factor
- If the symptoms warrant it, immobilization of the ankle and first metatarsophalangeal joint in a walking boot along with antiinflammatories
- If these fail, then a sonographic guided corticosteroid injection into the FHL sheath (but NOT into the tendon itself) or the os trigonum, if posterior impingement is present

Guidelines for Choosing Among Nonoperative Treatments

- It is important to know which of the three syndromes is present: FHL tendinitis, posterior impingement, or both. This can be difficult to determine.
- The diagnosis may require diagnostic injections of local anesthetics.
- Immobilization in a walking boot treats both conditions.

Surgical Indications

- Failure to respond to conservative therapy
- Symptoms severe enough to warrant surgical intervention
- Surgery should NOT be performed in the absence of discomfort simply to increase the plantarflexion in the ankle by removal of the os trigonum. The results will be disappointing in these cases.

FIGURE 41-7. An MRI study of acute FHL tendonitis showing fluid within the sheath extending upward behind the ankle.

- A diagnosed tear in, or rupture of, the FHL should be surgically decompressed and repaired.

Aspects of History, Demographics, or Exam Findings that Affect Choice of Treatment

- Posterior impingement can be treated by removal of the os trigonum or trigonal process either by a small posterolateral incision or by endoscopic excision.
- The open technique has a lower complication rate but a longer postop recovery.
- The author prefers the open technique for tenolysis and debridement or repair of the FHL because the posterior tibial nerve can be identified and protected with the medial approach and the os trigonum can also be removed at the same time.
- The author's results have been better in professional ballet dancers than in amateurs.

Aspects of Clinical Decision Making When Surgery Is Indicated

- Which of the two syndromes is present, or are both present?
- Are you going to do this endoscopically or open?
- In the open technique, posterior impingement alone can be corrected through a lateral incision, but FHL tendonitis or a combination of FHL tendonitis and posterior impingement should be approached through a medial incision so that the posterior tibial nerve can be protected.

Evidence

Hamilton WG: Stenosing tenosynovitis of the flexor hallucis longus tendon and posterior impingement upon the os trigonum in ballet dancers. *Foot Ankle* 3(2):74–80, 1982.

The earliest report of these syndromes in dancers.

Hamilton WG: Posterior ankle pain in dancers. *Clin Sports Med* 27(2):263–277, 2008.

Differential diagnosis and treatment of FHL tendonitis and posterior impingement in professional level dancers. (Level V evidence)

Hamilton WG, Geppert MJ, Thompson FM: Pain in the posterior aspect of the ankle in dancers. Differential diagnosis and operative treatment. *J Bone Joint Surg Am* 78(10):1491–1500, 1996.

A retrospective review was performed of the results of operative treatment of stenosing tenosynovitis of the flexor hallucis longus tendon or posterior impingement syndrome, or both, in 37 dancers (41 operations). The average duration of follow-up was 7 years. Twenty-six operations were performed for tendinitis and posterior impingement; nine, for isolated tendinitis; and six, for isolated posterior impingement syndrome. A medial incision was used in 33 procedures; a lateral incision, in six; an anterior and a medial incision, in one; and a lateral and a medial incision, in one. Thirty ankles had a good or excellent result; six, a fair result; and four, a poor result. The result was good or excellent for 28 of the 34 ankles in professional dancers, compared with only two of the six ankles in amateur dancers. This is still the definitive article on the subject. The results were better in the professional dancers than the amateurs. (Level IV evidence)

Kolettis GJ, Micheli L: Release of the flexor hallucis longus tendon in ballet dancers. *J Bone Joint Surg Am* 78(9):1386–1390, 1996.

Thirteen female ballet dancers had an operative release of the flexor hallucis longus tendon because of isolated stenosing tenosynovitis, and the results were reviewed after a mean duration of follow-up of 6 years. All of the patients danced at the advanced or professional level, and all had failed to respond to nonoperative management. Symptoms, which included pain and tenderness over the medial aspect of the subtalar joint, were exacerbated by jumping and by attempts to perform en pointe work. Crepitus was present in six patients, and triggering was present in three. No patient had evidence of a symptomatic os trigonum. Postoperatively, all patients participated in a formal physical-therapy program for a mean of nine weeks. All patients returned to dancing, within a mean of 5 months. Eight patients were professional ballet dancers, four were students at advanced ballet schools, and one had stopped performing ballet for reasons unrelated to the tenosynovitis of the flexor hallucis longus. No complications were noted in this series. We concluded that an operative release of the flexor hallucis longus is effective for the treatment of isolated stenosing tenosynovitis in female ballet dancers who place high demands on the foot and ankle and for whom non-operative treatment has failed. (Level IV evidence)

Niek van Dijk C: Anterior and posterior ankle impingement. *Foot Ankle Clin* 11(3):663–683, 2006.

Anterior ankle impingement is characterized by anterior ankle pain on activity. Recurrent (hyper) dorsiflexion is often the cause. Arthroscopic management with removal of the offending tissue provides good to excellent long-term results. In posterior ankle impingement, patients experience hindfoot pain when the ankle is forcedly plantarflexed. Trauma or overuse can be the cause. The trauma mechanism is hyperplantarflexion, Overuse injuries typically occur in ballet dancers and downhill runners, who report pain on palpation at the posterolateral aspect of the talus. On plain radiographs, an os trigonum or hypertrophic posterior or talar process can be detected. Surgical management involves removal of the os trigonum, scar tissue, or hypertrophic posterior talar process. In the case of combined posterior bony impingement and flexor hallucis longus tendinopathy, a release of the flexor hallucis longus is performed simultaneously. Endoscopic management is associated with a low morbidity, a short recovery time, and provides good/excellent results at 2 to 5 years follow-up in 80% of patient. This is a good paper discussing endoscopic treatment. (Level V evidence)

Sammarco GJ: Partial rupture of the flexor hallucis longus tendon in classical ballet dancers: two case reports. *J Bone Joint Surg Am* 61(1):149–150, 1979.

(Level IV evidence)

Sammarco GJ: Flexor hallucis longus injury in dancers and non-dancers. *Foot Ankle Int* 19(6):356–362, 1998.

Thirty-one cases of flexor hallucis longus injuries in 26 patients were treated over a 16-year period (1977-1993). Groups were divided into dance-related injuries (group I) and other causes (group II). The two groups were compared with regard to age, activity, duration of symptoms, operative findings, histopathology, and postoperative time to resumption of full activities. Twenty-seven cases required surgery for unsuccessful nonoperative treatment. In group I, 71% of patients had a partial longitudinal tear of the flexor hallucis longus compared with 30% in group II. Another common finding was isolated tenosynovitis (21% in group I and 53% in group II). Eight cases had magnetic resonance imaging

(MRI) evaluations before surgery. Clinical correlation was found to be an important factor in interpreting the MRI. Dancers tended to have symptoms for a longer period of time before seeking treatment than did non-dancers. Surgical correction of tenosynovitis, pseudocysts, and tendon tear yielded good or excellent results in 14 of 15 dancers and 9 of 11 nondancers. Surgical treatment of tendon tears and other pathologic tendon conditions gave consistently good results in patients with refractory flexor hallucis longus disease. This study noted a 71% incidence of longitudinal tears in the dancer group versus 30% in the nondancers. Good results were obtained in both groups. (Level IV evidence)

Multiple-Choice Questions

QUESTION 1. The "plantarflexion sign" will be positive for

A. FHL tendonitis only.
B. posterior impingement only.
C. Both conditions
D. Neither condition

QUESTION 2. Posterior impingement

A. is only seen in dancers.
B. is mostly seen in dancers.
C. is never seen in athletes.
D. usually accompanies FHL tendonitis.

QUESTION 3. Posterior impingement can lead to FHL tendonitis.

A. True
B. False

QUESTION 4. A documented partial tear in the FHL is best approached

A. through a lateral incision.
B. through a medial incision.
C. endoscopically.
D. Any of the above

Answer Key

QUESTION 1. Correct answer: **B** (see Abnormal Findings)

QUESTION 2. Correct answer: **B** (see Pathophysiology)

QUESTION 3. Correct answer: **B** (see Pathophysiology)

QUESTION 4. Correct answer: **B** (see Aspects of Clinical Decision Making)

BEYOND BASIC REHABILITATION: RETURN TO BALLET AFTER TREATMENT FOR FLEXOR HALLUCIS LONGUS TENDINOPATHY AND POSTERIOR IMPINGEMENT

William G. Hamilton, BSE, MD, AAOS, AOA, FACS, Marika Molnar, PT, LAc, and Nadia Sefcovic, DPT, COMT

ASPECTS OF BALLET THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

Unlike any other sport, the rules of the game are never the same in dance.

- Dancers are required to perform their art at the extremes of range, making return to activity challenging. Extreme plantar flexion (PF) of the ankle/foot complex is necessary so that the dancer can balance on the tips of the toes as well as be able to fully dorsiflex the hallux while in plantar flexion at the ankle in order to balance or push off from there.[1,2] Ankle dorsiflexion (DF) is essential for landing from big jumps, lunging, preparation for all turns, etc.
- The dancer must also regain strength and proprioception of the ankle/foot complex in these extreme ranges of motion. Acceleration, deceleration, and isometric holds are required.
- The dancer must be able to maintain strength, stability, and flexibility at the lumbopelvic and hip joints and the entire lower extremity in order to meet the demands of the choreography. For example ballet dancers must have adequate neuromuscular control in hip external rotation (i.e., turnout).
- Dynamic strength and alignment control will be important as the dancer returns to the studio. The dancer must be able to move with varying speeds, in various body positions, in all planes of movement and in all directions.
- Special attention must be paid to the type of shoe the dancer must wear in order to return to dance (i,e., pointe shoes, ballet slippers, jazz/character shoes, barefoot, etc.). Dancing barefoot or in ballet slippers usually requires more hallux dorsiflexion than other forms of footwear.

Introduction

- Posterior ankle impingement (PAI) is caused by compression of the tissues between the posterior tibia, talus, and calcaneus, which occurs in extreme ranges of ankle plantar flexion that dancers require to achieve en pointe and demi-pointe positions.[2,3,4]
- Osseous or soft-tissue can be impinged in PAI. Causes of osseous impingement include an os trigum, Stieda's process, or anatomical variations in the posterior aspects of the tibia or calcaneous.[2,5] Soft tissue impingement causes can include various structures including: the capsule or synovium of the subtalar or talocrural joints; ligaments such as the posterior talofibular ligament, the posterior intermalleolar ligament, or the posterior tibiotalar ligament; or tendons such as the flexor hallucis longus (FHL) as it passes from the fibula, crossing the posterior talus, and running through the fibroosseous tunnel.[2,3,5]
- Repetitive plantar flexion required of dancers can also cause FHL tendinopathy. Dancers can develop irritation and swelling of the tendon or the tendon's sheath.[5] This irritation to the tendon and sheath causes pain and limited motion as the musculotendinous unit hypertrophies.[6] The dancer will have resultant tendon and muscular weakness secondary to pain and disuse of the muscle. As this becomes a chronic condition the tendon can develop adhesions, calcifications, and nodules at the musculotendinous junction as part of the degenerative process.[7]
- Flexor hallucis longus injury is very common in dancers, both male and female. Most dance movements require the use of the FHL as the foot and ankle go through plantar and dorsiflexion thousands of times per day. When the foot is in plantarflexion, the FHL functions as a stabilizer[8] and eccentrically it restrains dorsiflexion at the first metatarsophalangeal joint as well as eccentrically controlling calcaneal eversion.[7] As the dancer is landing a jump or in grand plié, the FHL is stretched between the posterior talar tubercles and the sustentaculum tali.[7]
- Flexor halluces longus tendinopathy and posterior ankle impingement are separate injuries, but often they occur in combination.[6]
- Posterior impingement pain is usually posterolateral to the ankle joint;[3] pain, tenderness or swelling posterior to the medial malleolus is experienced with FHL tendinopathies. The dancer also can experience triggering of the toe or crepitus of the FHL tendon, which can be palpated at the tendon sheath when the dancer moves their hallux.[6,7]
- Although posterior impingement and FHL tendinosis are seen in both genders, these injuries seem to be more problematic for females and pointe dancers.[3] Female dancers who are on the professional track will usually have their os trigonum removed as it interferes with their ability to go up onto pointe. Once the surgical site is healed the rehabilitation follows the same course as outlined if it was a simple bony removal.
- A common precursor to posterior ankle impingement is ankle instability resulting from an ankle sprain.[2,9,10] If a lateral ankle sprain precedes these injuries it usually takes longer to rehabilitate owing to laxity in the ligaments, which then allows for excessive anterior displacement of the talus. This excessive motion will need to be controlled to provide more boney stability. Often when there is boney instability and ligamentous laxity, this will lead to muscle overactivity that can lead to tendinopathies.[11] Stability of the ankle as well as proprioception must be addressed in the dancer's rehabilitation in addition to addressing the stability role of the FHL in the medial longitudinal arch and great toe.[7,12,13]
- Generally if these injuries are treated appropriately with a conservative physical therapy program including sufficient relative rest and appropriate exercises, all usually return to dance.[4,5,6]
- If conservative therapy does not return the dancer to full function, surgical repair of tendon or removal of extra bone or scar tissue in the posterior ankle may be necessary;[6] the dancer can usually return to full participation once all rehabilitation criteria have been met.

Phase I (Weeks 1 to 2): Advanced Strength and Conditioning Programs

Periodization

- Linear

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Appropriate alignment for dance technique is immediately integrated into phase I of the protocol, and done so in a limited weight-bearing position so the patient can focus on proprioception and neuromuscular reeducation during the exercises.
- During this phase the dancer is in a relative rest period. This means that the dancer will not participate in dance class, but will begin to focus on proper dance technique and alignment in physical therapy.
- FHL is eccentrically strengthened with dance-specific movements, but done so in a low-load situation to ensure proper dance technique and motor control training.

Training Continuum

See Box 41-1 for definitions of the dance-specific terminology used throughout this discussion. Additional definitions of ballet terminology may be found at http://www.abt.org/education/dictionary/index.html.

- Flexibility/joint mobility for joint stability
  - Active range of motion (AROM): non–weight-bearing wall program (Figure 41-8) including toe/ankle dissociation during PF and DF, doming, relevé
  - Soft tissue mobility: FHL release at proximal end, effleurage of posterior talocrural joint (TCJ) with dancer in prone, transverse friction massage to FHL if appropriate
  - Joint mobilization: posterior TCJ mobilization Gr II-IV, subtalar joint (STJ) inversion/eversion mobilization

  - Joint: If needed: first ray mobilization into PF, first metatarsophalangeal joint (MTPJ) into extension, distal and proximal tibia/fibula joint mobilization, tibia/femoral joint mobilizations
  - Taping to prevent all hallux joints from flexing during ankle PF (Figure 41-9)
  - Mobility of FLH tendon to slide in tunnel—gentle PROM of FHL in various ankle positions
  - If history of ankle sprain is present with posterior ankle impingement—ankle taping and ankle stabilization program and peroneal and tibialis posterior muscle strengthening
- Training with optimum posture
  - Alignment above and below site of injury
- Sensorimotor and balance training
  - Single limb stance (SLS) with eyes open and using port de bras, ensuring toes don't flex at interphalangeal joints (IPJs) (Figure 41-10)
  - SLS with eyes closed
- Core training
  - Supine: local and global muscle recruitment and strengthening progressing to standing abdominal stabilization (Figure 41-11)
- Cardiorespiratory/cross- training
  - Bike, swim, elliptical, Pilates, yoga
- Multiplanar training activities
- Training for optimum muscle balance
  - Pointing OKC: use of gastrocnemius/soleus as well as posterior tibialis and FHL/peroneus longus sling to PF ankle and flexor halluces brevis to flex first MTPJ, but not allowing the IPJ to flex
- Training for optimum muscle functional strength
  - OKC and CKC hip ER strengthening and gluteus medius strengthening
  - Eccentric FHL strengthening lower from full pointe rolling through demi-pointe to demi-plié. Initially done with feet on the wall, then progress to sitting (Figure 41-12).

TIMELINE 41-1: **Rehabilitation of Flexor Hallucis Longus Tendinopathy and Posterior Impingement**

PHASE I (Weeks 1 to 2)	PHASE II (Weeks 3 to 7)	PHASE III (Weeks 7 to 12)
• PT modalities to decrease inflammation and pain • AROM—wk 1: ankle and toe dissociation of DF & PF—on the wall • AROM—wk 1: foot intrinsic strengthening of DF & PF—on the wall • PROM FHL in various ankle positions • Mobilizations as needed • Single limb stance (SLS) eyes open and using port de bras • SLS eyes closed • Eccentric FHL strengthening—wk 1: on the wall • Eccentric FHL strengthening—wk 2: sitting • Neuromuscular reeducation exercises • OKC and CKC gluteus medius exercises • Gastroc & soleus flexibility • Gait training	• AROM: ankle and toe dissociation of DF & PF—wk 3—seated • AROM: CKC DF (pliés)—wk 3—on the reformer • Flexibility—FHL stretching—wk 3–7 • Eccentric FHL strengthening: Double leg elevé—wk 3– seated • Intrinsic foot strengthening: Doming—wk 3—seated • Eccentric FHL strengthening: Lowering from full pointe to demi-pointe—wk 3 standing • AROM: CKC DF (pliés)—wk 4—standing • Intrinsic foot strengthening: Doming—wk 4—standing • Eccentric FHL strengthening: Double leg relevé & elevé—wk 4—on reformer • Neuromuscular re-education: OCK ankle and toe dissociation of PF (tendus)—wk 4—standing • AROM: Single leg CKC DF (fondu)—wk 5—on the reformer • Eccentric FHL strengthening: Relevé & elevé, ascend on two legs, descend on affected leg in parallel—wk 5—on reformer • AROM: Single leg CKC DF (fondu)—wk 6—standing • Eccentric FHL strengthening: Single leg relevé & elevé—wk 6—on reformer • Eccentric FHL strengthening—wk 7: double leg relevé & elevé in standing in parallel and turn-out • Plyometrics: Simulate push-off and deceleration of landing a jump performed in a lunge position—wk 7—standing lunge • Proprioception & balance—progressing to uneven surfaces—wk 3–7 • Hip ER OCK & CKC PREs—wk 3–7 • Gait training—wk 3–7 • Mobilizations as needed—wk 3–7 • PT modalities as needed—wk 3–7	• PT modalities as needed • Mobilizations as needed • AROM—full weight-bearing ankle PF (90° for a ballet dancer) with hallux ext (90° for a ballet dancer) • Relevés & elevés—wk 7: double leg parallel & turn-out—standing • Relevés & elevés—wk 8: ascend on two legs, descend on affected leg parallel & turn-out—standing • Relevés & elevés—wk 9: single leg parallel and turn-out—standing • Dance specific—wk 10: turning technique • Plyometrics—wk 10: progressing from double leg to single leg—on reformer • Plyometrics—wk 11: progressing from double leg to one leg to the other—standing • Plyometrics—wk 12: progressing to single leg—standing • Proprioception & Balance—in CKC PF • Gait training

BOX 41-1 Glossary of Dance Terminology

TERM	DEFINITION
allegro	Rapid tempo movements, often includes jumping steps. Petit allegro includes smaller jumping steps. Grand allegro includes large expansive jumps such as grand jeté.
barre	The introductory/warmup portion of the ballet class, conducted while holding onto a ballet bar. The dancer always starts with the left hand at the bar, working the right gesture leg.
beats	To hit the legs together, moving in and out of fifth position in the air. See petite batterie.
center floor	The second portion of the ballet class, comprised of the adagio, turns, and small jumps (petit allegro)
dégagé	"To disengage." Sharp brushes of the pointed foot to develop speed and precision of the feet and legs.
demi	Half. As in demi-plié
dèveloppé	A large, relatively slow leg gesture. The gesture limb begins from first or fifth position, passes through passé, to extend at 90° or higher to the front (en avant), side (a la seconde), or back (en arrière—arabesque).
elevé	A rise upward onto the toes
frappé	Beginning from the cou-de-pied position, a rapid striking ricochet (off the floor) of the gesture foot, ending in a pointed position. Develops strength and precision of the gesture limb
grand	Large
grand battement	A large, swift leg "kick" with the knee extended and foot pointed. Performed to the front, side, or back and from first, fifth, or the point tondu.
penché	Inclined. Usually arabesque penché, in which the torso and gesture limb are tilted forward from the hip. This directs the torso and focus toward the floor.
petite	Small, little
plié	A bend of the knees while the torso is held upright. The action relies on varying degrees of hip and knee flexion, with ankle and MTP dorsiflexion, depending on whether the plié is demi- or grand.
pointe, en	On pointe. Position of the foot in a pointe (or toe) shoe, in which the dancer stands on the toes
port-de-bras	Carriage of the arms. The codified arm positions that provide strength and balance to the trunk, and may also serve as gesture or enhancement of focus.
relevé	A rise or spring onto the toes (demi- or full pointe) from plié.
ronde de jambe	A unilateral leg action in which the gesture leg is circled from front to back of the dancer's body, or vice versa. May be performed on the ground (a terre) or in the air (en l'aire).
tendu	A "stretched" action of the gesturing limb from a stance position with flat foot to a pointed foot, with the toes keeping contact with the floor

Compiled by the Practice Committee, Performing Arts Special Interest Group, Orthopaedic Section, APTA, January, 1998. (http://www.orthopt.org/downloads/PAglossary.pdf)

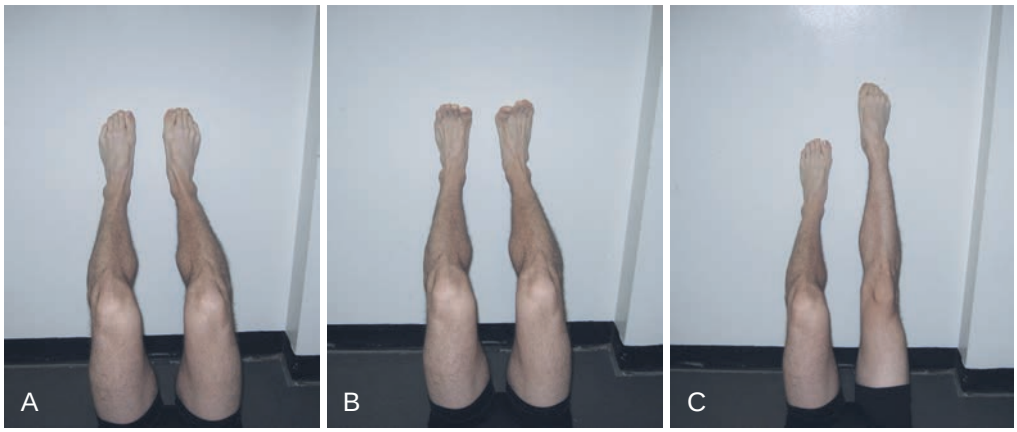

FIGURE 41-8. Non–weight-bearing wall program: doming. **A,** Right foot doming; ankle dorsiflexion, MTP joint plantar flexion. In the supine position he is able to keep correct alignment of his lower leg as he learns to use his intrinsic. **B,** Toe extension. **C,** Plantar flexion at ankle with MTP joint plantarflexing (doming).

.(**FIGURE 41-9.** Taping to prevent IP flexion (mainly proprioceptive feedback

FIGURE 41-10. Single-leg port de bras. **A,** Moving the arms through ballet arm positions. **B,** Single leg without gripping toes. **C,** Single leg gripping IP joints, a poor strategy.

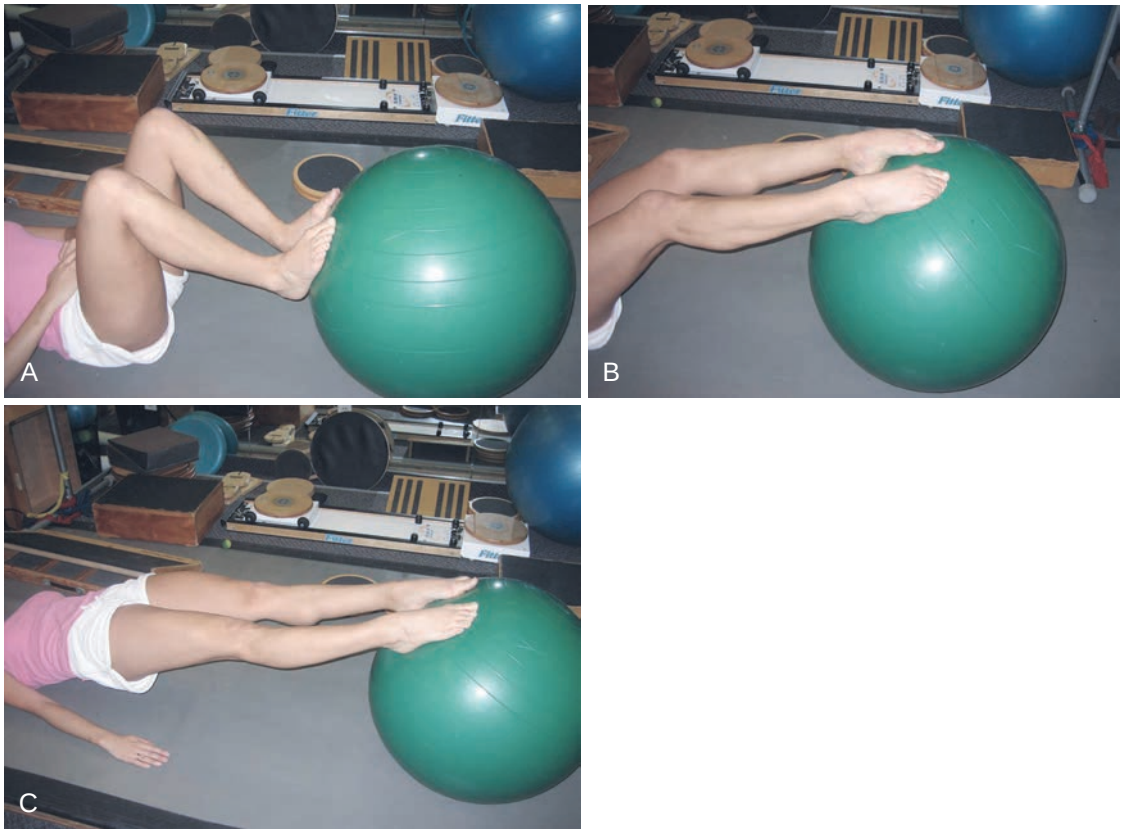

FIGURE 41-11. Local and global muscle recruitment. **A,** Starting position in full dorsiflexion at ankle. **B,** Full plantar flexion at ankle and MTP joints. **C,** Strengthening local and global muscle groups.

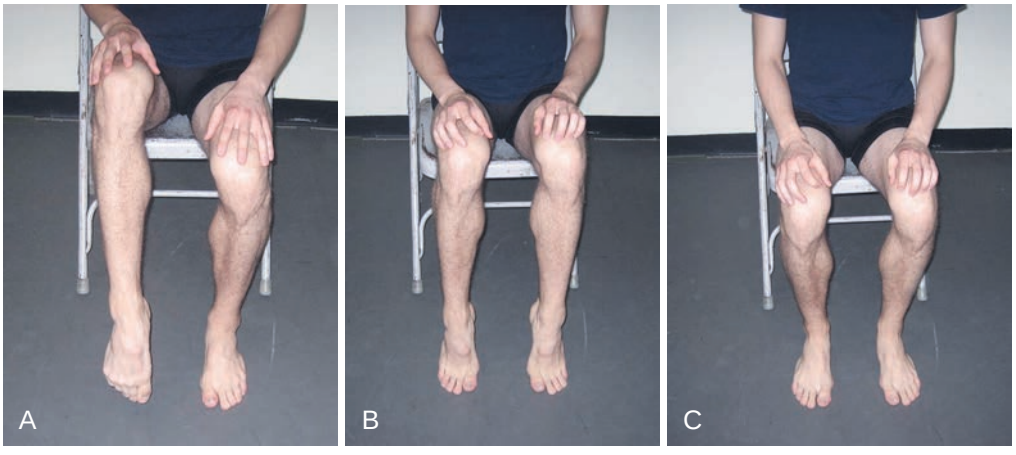

FIGURE 41-12. Eccentric FHL strengthening while sitting. **A,** Eccentric rolling through FHL from full plantar flexion. **B,** Full plantar flexion at

- Neuromuscular dynamic stability exercises
  - Main focus is reeducation for PF without gripping toes (flexing the MTPJs and IPJs) and implementing foot intrinsic strengthening program initiating on the wall and progressing to sitting by end of second week
    - Isolating PF at the TCJ joint (tendu on the wall) (see Figure 41-8C)
    - PF at the ankle, MTPJ flexion, not allowing IPJ to flex
    - Dome foot and slide into tendu
    - Tendu to ball of foot then dome
    - Pointe, roll through to ball of the foot, roll through to demi-plié (not allowing IPJs to flex)
- Functional training
  - Gait reeducation

Training Principles Used in the Design of the Program

- Principle of progression

Application of Acute Training Variables

- Repetitions: 10 to 15
- Sets: 3
- Rest interval: 10 seconds between each set
- Intensity: low to moderate intensity
- Repetition tempo: slow; this phase focuses on motor control and neuromuscular reeducation; often when dancers increase their tempo they return to poor technique habits that contribute to FHL tendinosis and irritation of posterior ankle joint.
- Training frequency: daily, alternating cross-training with cardio; and other exercises specific to injury rehab daily × 3
- Training duration: 10 min per set
- Specific exercises used in the training: as above

Phase II (Weeks 3 to 7): Performance Enhancement Training Techniques

Periodization

- Linear

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Appropriate alignment for dance technique, especially ballet barre, is integrated into phase II of the protocol, and done so initially in a limited weight-bearing position (a flat ballet barre can be integrated initially, meaning NO relevé activities); then progressing to relevés on a Pilates reformer and finally standing (Figure 41-13).

This is done so the patient can focus on proprioception and neuromuscular reeducation during the exercises while functionally strengthening FHL eccentrically.

Training Continuum

- Flexibility/joint mobility for joint stability
  - ROM: OKC and CKC PF to DF (without flexing IPJs) starting in seated position PWB before moving into WB: on ball or reformer
  - Joint: posterior TCJ mobilization Gr IV-V, STJ inversion/eversion mobilization (Figure 41-14)
    - Joint: If needed, first ray mobilization into PF, first MTPJ into extension, proximal fibula/tibia, tibia/femoral

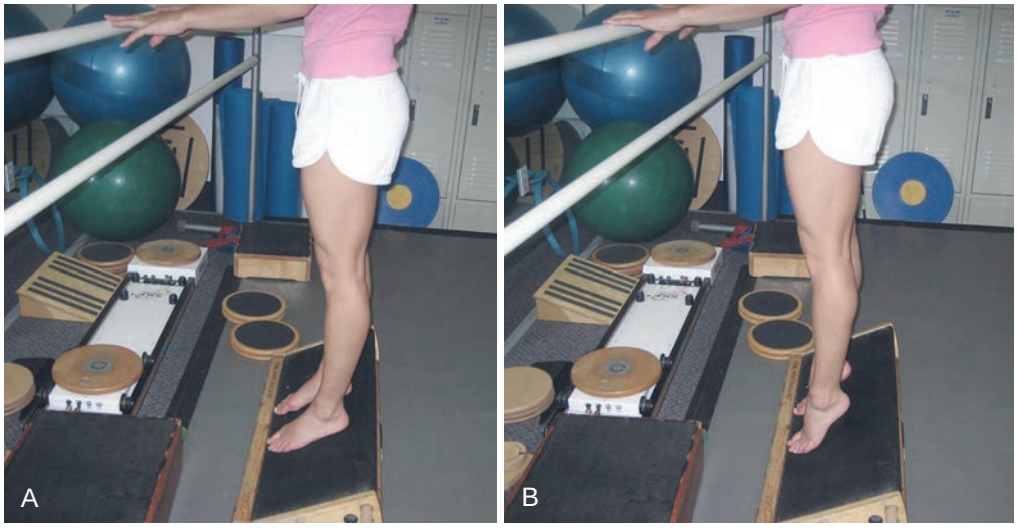

FIGURE 41-13. A, Strengthening at end range. **B,** Standing, end range strengthening.

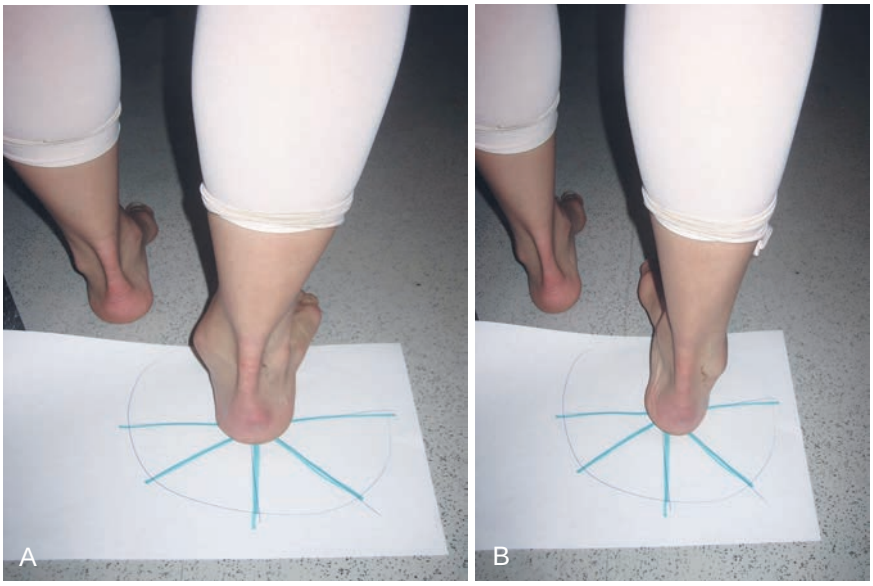

FIGURE 41-14. Heel clocks for mobilization of subtalar joint. **A,** Eversion. **B,** Inversion.

  - Soft tissue mobility: FHL, possibly gastrocnemius/soleus, transverse friction massage (if appropriate); dancer should contract/relax FHL during friction
  - Flexibility of FLH—stretch FHL: Stand with the hallux extended against a wall and the ball of the foot on the floor, dorsiflex the ankle. Hold stretch for 30 seconds (Figure 41-15).
  - If history of ankle sprain is present with posterior ankle impingement—ankle taping and ankle stabilization program and peroneal and tibialis posterior muscle strengthening
- Training with optimum posture
  - Dynamic posture of lumbopelvic girdle during movements of hip and lower extremity
- Sensorimotor and balance training
  - On uneven surfaces with opposite lower extremity performing dance specific movement (e.g., frappe)
  - On double leg relevé by end of phase (Figure 41-16)
- Core training
  - Weight bearing Pilates, etc.
  - Plank
- Cardiorespiratory training
  - Bike, swim, elliptical
  - Step-up at quicker pace, increase by adding port de bras
- Multiplanar training activities
  - Initiate plié, elevé, relevé activities on reformer in turn-out
  - Initiate tendu and OKC PF in turn-out
- Training for optimum muscle balance
  - Standing dome
  - Dome and DF ankle (in sitting and progress to standing and plié)
- Training for optimum muscle functional strength
  - Reformer
    - Relevé progression (double leg, then progress to up on two-down on one, then progress to single leg) (Figure 41-17)
      - Note: It is easier to work in pointe shoes than in flat ballet slippers because it lessens rolling through the foot.
    - Elevé progression (double leg, then progress to up on two-down on one, then progress to single leg)

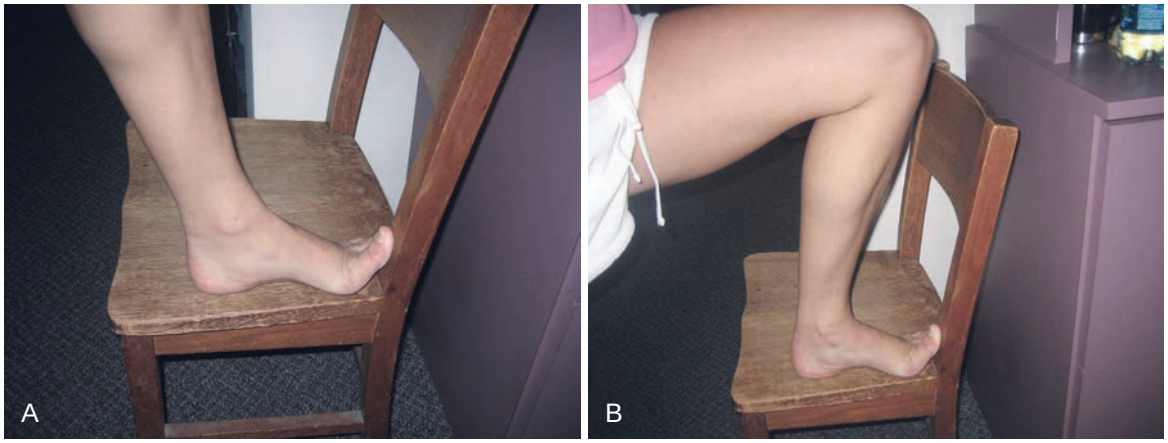

FIGURE 41-15. Improving FHL flexibility. **A,** Stand with the hallux extended against a wall or firm surface and the ball of the foot on the floor. **B,** Dorsiflex the ankle. Hold stretch for 30 seconds.

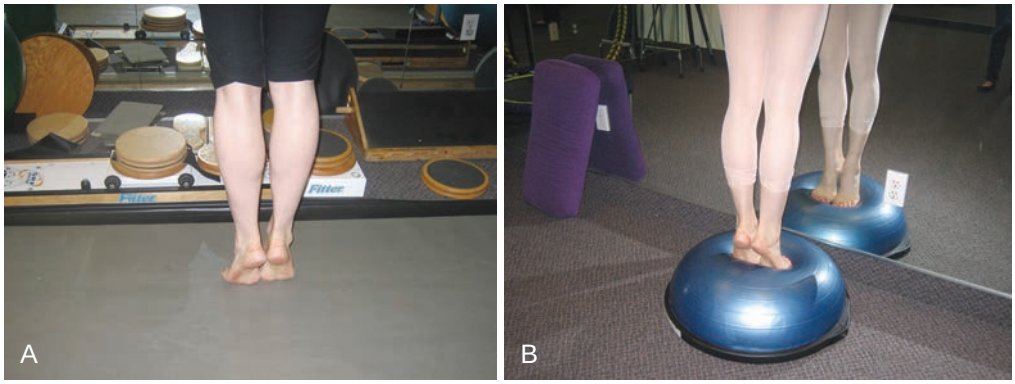

FIGURE 41-16. Reformer training. **A,** Double leg in pointe shoes. **B,** Single leg in pointe shoes.

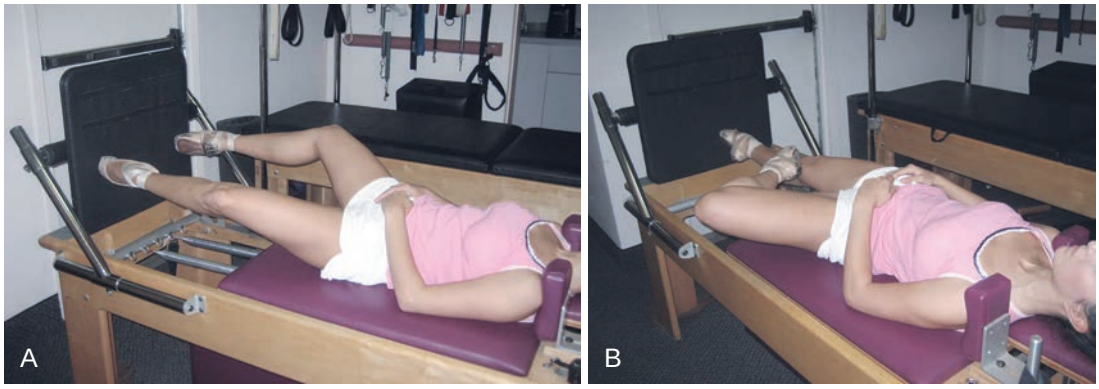

FIGURE 41-17. Double-leg relevé. **A,** Parallel. **B,** On uneven surface.

- FHL: Eccentric FHL strengthening lower from full pointe rolling through demi-pointe to demi-plié. Standing on right leg, go to full pointe on the left foot, rolling through demi-pointe to demi-plié. Repeat on other side in parallel and turned out (Figure 41-18).
- Training for optimum muscle functional power
- Neuromuscular dynamic stability exercises
  - Lunge exercise training push-off and deceleration control
  - Single leg pliés with correct alignment
- OKC and CKC hip ER strengthening and gluteus medius strengthening
- Training for speed, agility, quickness: vary the speed and timing of exercises
- Plyometric training
  - Lunge exercise training push-off and deceleration control
- Functional training: Begin basic barre in parallel and turn-out (Figure 41-19).
  - Initially this will include a flat ballet barre, (see activities in sport-specific training) the dancer will not perform grand pliés, relevés, or elevés. Gradually add in double leg demi-pointe activities (grand plié, relevé, and elevé) into barre. By the end of this phase, the dancer can progress to a ballet barre including leg demi-pointe activities as long as relevé and elevé activities are pain free.
- Sport-specific training
  - Flat barre—no relevé or elevé: slow tempo to start progressing to moderate
  - Demi-plié
  - Tendu (Figure 41-20)
  - Dégagé
  - Frappé
  - Rond de jambe
  - Dèveloppé (Figure 41-21)
  - Battement
- Additional types
  - Gait

Training Principles Used in the Design of the Program

- Principle of progression

Application of Acute TraIning Variables

- Repetitions: 8 to 10
- Sets: 3
- Rest interval: 10 seconds
- Intensity: moderate
- Repetition tempo
- Training frequency: daily
- Training duration: 30 to 45 minutes per set
- Training volume
- Specific exercises used in the training

Phase III (Weeks 7 to 12): Sport-Specific Training

Periodization

- Linear

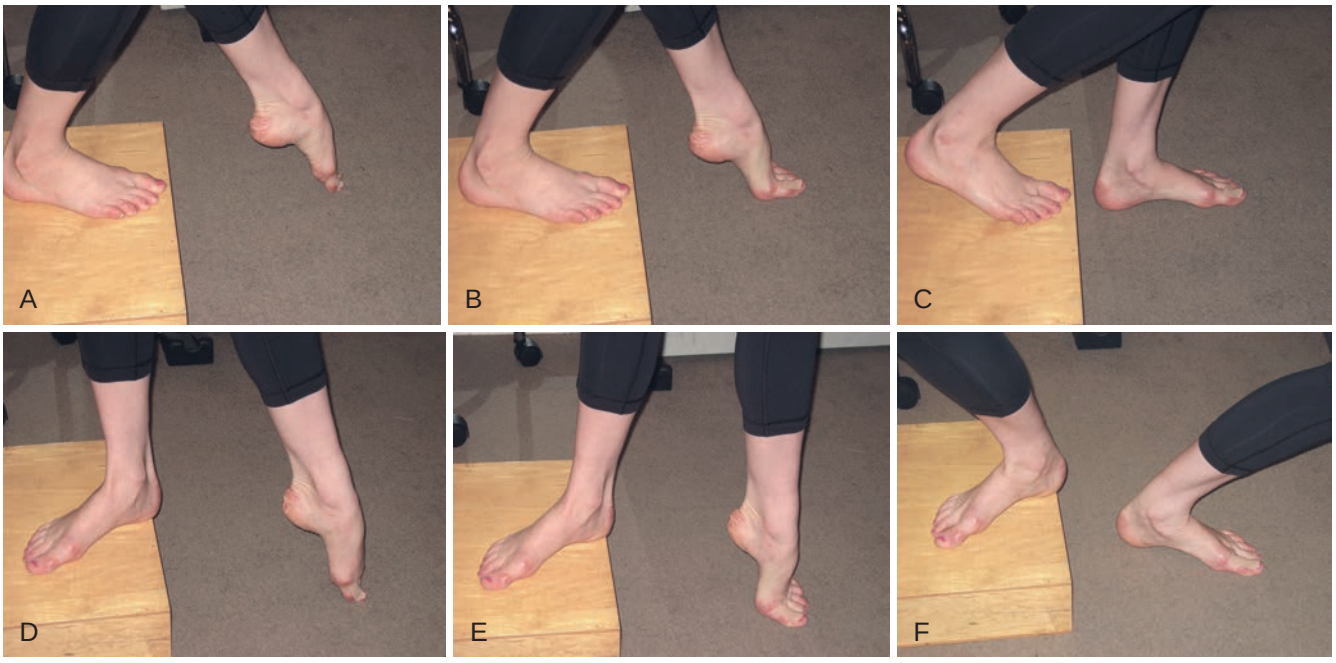

FIGURE 41-18. Eccentric FHL strengthening lower from full pointe rolling through demi-pointe to demi-plié. **A,** Standing, full weight bearing load: Eccentric FHL to retrain deceleration in parallel. **B,** Standing Eccentric FHL strengthening. **C,** Eccentric FHL strengthening. **D,** Eccentric load FHL—Turned out deceleration sequence. **E,** Eccentric load FHL-turned out deceleration sequence. **F,** Eccentric load FHL—turned out deceleration sequence.

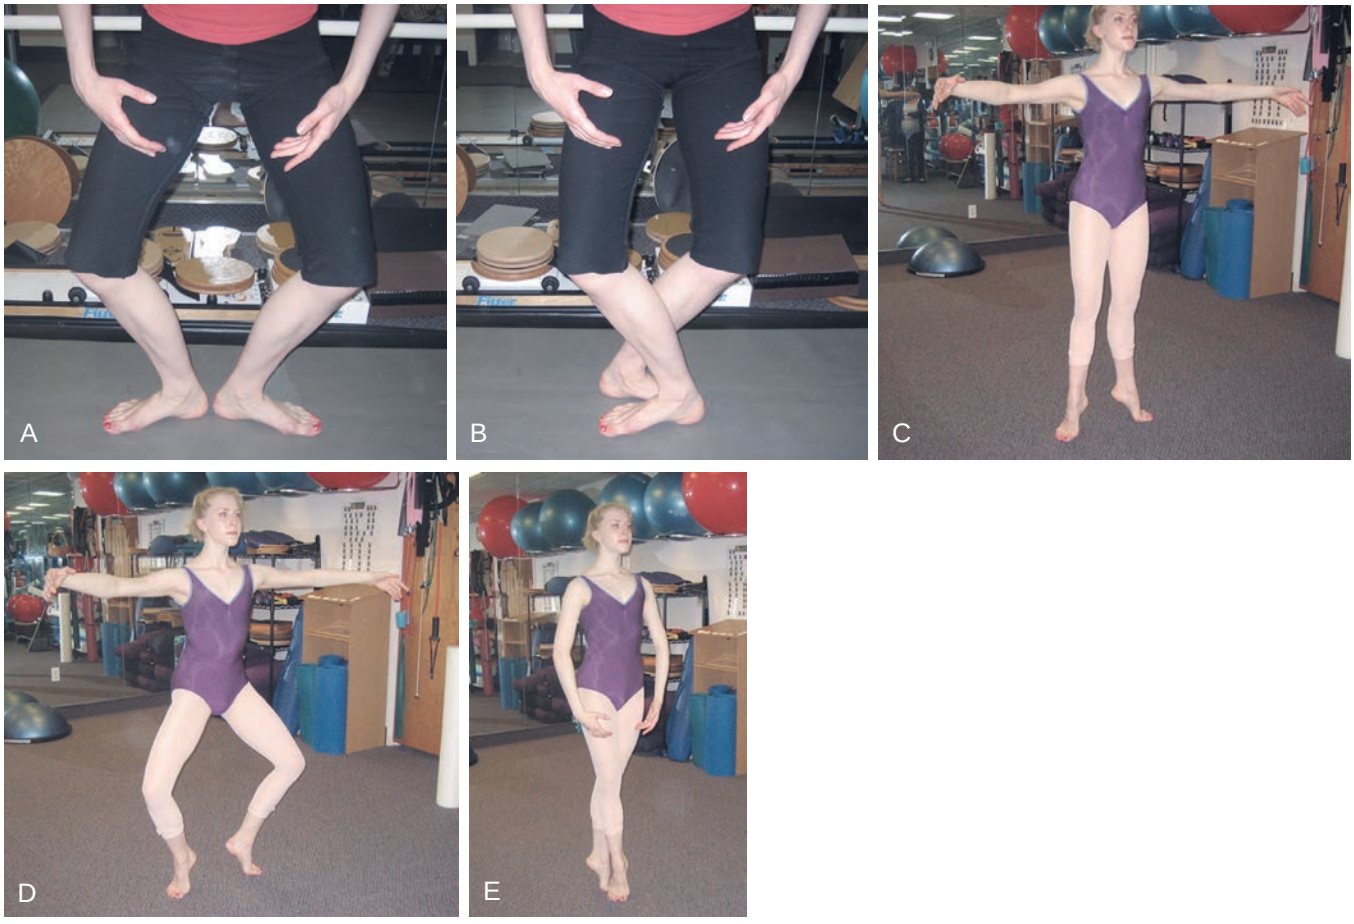

FIGURE 41-19. Functional training. Initially, flat barre. **A,** First position plié. **B,** Fifth position plié. **C,** Progress to relevé work on two feet: first position. **D,** First position with bent knees (more challenging). **E.** Fifth position relevé.

FIGURE 41-20. Flat barre tendu. **A,** Front. **B,** Side. **C,** Back.

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- Dance technique is integrated during phase III by progressing from ballet barre into center. The continued focus is on proprioception and neuromuscular reeducation during more dynamic exercises to ensure appropriate functional use of the foot and ankle musculature while in full weight bearing.

Training Continuum

- Flexibility/joint mobility for joint stability
  - ROM—Full weight bearing ankle PF with hallux extension
  - Joint: Posterior TCJ mobilization Gr IV-V, STJ inversion mobilization
    - Joint: If needed, first ray mobilization into PF, first MTPJ into extension, proximal fibula/tibia, tibia/femoral
  - Soft tissue mobility: FHL, possibly gastrocnemius/soleus
    - If history of ankle sprain is present with posterior ankle impingement—ankle taping and ankle stabilization program and peroneal and tibialis posterior muscle strengthening
- Training with optimum posture
- Sensorimotor and balance training[6]
  - On uneven surfaces with gross movement such as penché (Figure 41-22)
  - Medial/lateral ankle stability on half foam roller
  - On single leg elevé by end of phase
- Core training
  - Weight bearing
  - Plank
- Cardiorespiratory training
  - Bike, swim, elliptical
  - Step-up at quicker pace increase by adding port de bras
- Multiplanar training activities
  - Initiate center dance activities moving in and out of different planes
- Training for optimum muscle balance
- Training for optimum muscle functional strength

FIGURE 41-21. Dèveloppé in center.

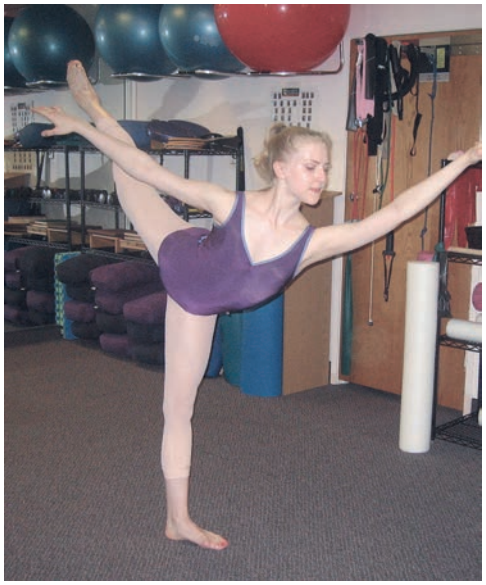

FIGURE 41-22. Penche arabesque.

  - Standing
    - Elevé progression without the support of the ballet barre (double leg, then progress to up on two-down on one, then progress to single leg)
    - Relevé progression without the support of the ballet barre (double leg, then progress to up on two-down on one, then progress to single leg)
- Training for optimum muscle functional power
  - Concentric and eccentric use of FHL while performing jumps on the Pilates reformer. Initiate with double leg jumps, then progress to jumping off one foot and landing on two feet, next progress to jumping off one foot and landing on the other, then jumping off and landing on the same foot, finally progressing to jumping off two feet and landing on one foot. Jumps should be practiced in parallel as well as turn-out.
- Neuromuscular dynamic stability exercises
  - CKC PF with hallux extension
  - FHL eccentric control landing jumps on reformer
  - Pointe work at ballet barre
- Training for speed, agility, quickness
  - Initiate faster PF activities.
  - Add petite allegro.
- Plyometric training
  - Initiate on reformer or in a pool.
    - Initiate with double leg jumps, then progress to jumping off one foot and landing on two feet; next progress to jumping off one foot and landing on the other, then jumping off and landing on the same foot, finally progressing to jumping off two feet and landing on one foot. Jumps should be practiced in parallel as well as turn-out.
  - Progress the above to full weight bearing
  - Add speed component
  - Add height and complexity—beats, revolutions, etc.
- Functional training
  - Focus on foot pushing off and landing, especially to control deceleration.
  - Focus on eccentric control of FHL in a pointe shoe.
- Sport-specific training
  - Progress from barre in flat shoes to barre en pointe.
  - Add class through adagio.
  - Then progress to add turns in class.
  - Then progress to add jumps in class.
- Additional types
  - Gait

Training Principles Used in the Design of the Program

- Principle of progression
- Principle of overload
- Principles of specificity—specific adaptation to imposed demands

Application of Acute Training Variables

- Repetitions—increased reps for endurance
- Sets 3 to 5
- Rest interval none
- Intensity low to high
- Repetition tempo—faster paced
- Training frequency daily
- Training duration 1 to 2 hours/day
- Training volume
- Specific exercises used in the training: ballet technique

Sports Performance Testing

General Information

- General history
  - What are your symptoms?
    - Location of pain
    - Type of pain
    - How does your pain react to rest?
  - Onset of symptoms?
    - When? Is it a chronic or acute problem?
    - Cause? Insidious, or increase in dance load?
  - What increases symptoms?
  - What decreases symptoms?
  - How do your symptoms change throughout the course of the day?
  - How do your symptoms change throughout the course of a dance class?
  - What are the dancer's goals?
- Subjective questionnaires (Figure 41-23)
  - Visual analog pain scale
  - Menstruation history
- Medical history
  - History injuries
  - Medications, vitamins, supplements, drug use
  - Have you ever been hospitalized?
  - Are you seeking treatment for an ongoing medical condition?
  - Benign joint hypermobility syndrome
  - Anomalies
- Sports injury history
  - Is there a history of ankle sprains?
  - History of tendinitis and/or tendinosis
  - Have you had an x-ray on pointe or demi-pointe that reveals an os trigonum or a form of osseous posterior ankle impingement?
- Surgical history
  - Have you had an os trigonum removed in your other ankle?
- Chronic conditions/medication
  - Asthma
  - Diabetes
  - Any conditions requiring chronic use of steroids

Objective Tests

- Physiological assessments
  - AROM
    - DF, PF, open kinetic chain & closed kinetic chain
    - Hallux extension—open kinetic chain and functional hallux ROM in weight bearing
    - Thomasen test[14]
      - A positive Thomasen sign occurs when extension of the first MTPJ is normal when the ankle is plantarflexed, but disappears when the ankle is dorsiflexed (as in a grande plié in first position). It is caused by muscle fibers on the FHL

Age you began dancing: _____ Type of dance you do: _____

Age you began pointe work: _____

Formal dance training: School: _____ Number of years: _____

School: _____ Number of years: _____

Present dance training and number of classes/week: _____

_____

Are you performing now? _____ Name of company: _____

Type of shoes worn: _____ Type of floor surface you dance on: _____

Number of years you have been dancing as a professional: _____

Major injuries or illnesses throughout your career:

DATE	TYPE OF INJURY	WHOM SEEN	COURSE OF TREATMENT	RECOVERY

Special Questions for Women

1. At what age did you start menstruating? _____

2. Are your cycles regular? _____ Explain: _____

3. Are the symptoms of your *current injury* associated with your menstrual cycle either around the 14th day (ovulation) or at the onset of menses? _____

4. Do you notice a change in flexibility at either of these times? _____

5. Circle any premenstrual symptoms: Water retention Mood swings Headaches Food cravings Tender breasts Other _____

6. What type of birth control do you use? _____

7. Number of pregnancies: _____ Vaginal births: _____ Ceasarean births: _____

Episeotomy: _____ Numbness in pelvic area: _____

Problems related to pregnancy: _____

8. Do you currently experience leakage of urine? _____ If yes, circle when it occurs: Jumping coughing Sneezing Laughing During intercourse When putting key in door

9. Do you have any pelvic pain? ____ If yes, what activity brings it on? _____

10. Have you had any of the following (circle)? Retroverted uterus Fibroids/tumors Endometriosis Overian cyst Pelvic inflammatory disease Osteopenia Osteoporosis Diabetes

11. Have you gone through menopause (Y/N) or perimenopause (Y/N)?

12. Are you taking any medications, herbs or supplements for hormone replacement? _____ If yes, list them: _____

FIGURE 41-23. Subjective questionnaire for dancers and those with dance injuries.

tendon that attach abnormally far down and impinge on the entrance of the FHL tunnel. It is often found in dancers who are asymptomatic, so it is NOT a pathological sign, but more of an anatomical anomaly. It may be found in association with FHL tendinopathy.

- Special Tests
  - Tinnel's test at tarsal tunnel
  - Hyper plantar flexion test[15]
  - Palpation: Tenderness: posterior-lateral ankle with an os trigonum or posteromedial ankle (tarsal tunnel area) with FHL tendinopathy[15]
  - Swelling: posterior TCJ
  - Thickness: lateral tubercle of the posterior talar process
  - Crepitis: FHL at tarsal tunnel
  - Trigger toe
  - Warmth: posterior TCJ

- Strength
  - Manual muscle test foot intrinsics and extrinsics
- Cyriax selective tissue tension test, especially to rule out posterior tibialis tendinopathy. This assesses AROM, PROM, resistive tests, and palpation. The ROM tests the patient's willingness to move, the available AROM, and the muscular power available. Resistive movements can assess the status of the contractile structures around the joint. PROM test noncontractile structures. Palpation is performed to detect any deformity or inflammatory signs, including warmth or swelling.
- Anterior and posterior draw
  - If positive perform specific ligament tests
- Talar swing test (Pettman course notes).
- Joint glides
  - Foot and ankle as well as proximal fibula/tibia and tibia/femur

- Body composition tests
- Static/dynamic postural assessments
  - Qualitative standing postural assessment
    - Examples:
      - Does the dancer have genu recurvatum?
      - Is the dancer able to stand and walk in parallel or does she/he have excess toe out while walking and in a static stance?
      - Is there noticeable intrinsic foot muscle atrophy?
      - Is the muscle bulk in the gastrocnemius and soleus equal side to side?
      - What foot type does the dancer have (Grecian, pheasant, etc.)?
      - Is the dancer's foot pes planus or pes cavus?
- Dynamic muscle performance testing
  - Resist FHL in full ankle PF with hallux fully extended (relevé position) lowering to CKC DF (demi-plié)
- Movement performance testing
  - Double leg relevé/plié
  - Single leg relevé
  - Single leg plié
  - Jumps
- Sport-specific testing
  - Technique assessment of
    - Relevé
    - Plié
    - Tendu
    - Jumps
- Others
  - Pointe shoe assessment

Specific Criteria for Progression to the Next Stage to Determine Readiness for Ballet

- Phase I
  - Pain is decreased
  - Full open kinetic chain ankle AROM DF & PF pain free
  - FHL manual muscle test is pain free
  - Able to ambulate and roll through foot without pain
- Phase II
  - Manual muscle test of FHL is 5/5 without pain
  - Able to tolerate 20 single leg relevés on reformer without pain
  - Able to tolerate full ballet barre without pain
- Phase III
  - Full weight-bearing PF—25 repetitions without pain
  - 50 repetitions of tendu without pain
  - 25 single leg jumps without pain

Specific Criteria for Release to Unsupervised Complete Participation in Ballet

- Return to full class, and if no exacerbation then dancer is able to return to rehearsal or performance

Recommended Ongoing Exercises

- Intrinsic foot exercise progression
  - Doming for the lumbricals: Initiate in sitting or with feet on the wall (note that if the dancer cannot perform toe flexion at the MTPJs while keeping the IPJs in neutral, a towel roll can be placed under the heel to help facilitate the exercise). This should be progressed to standing on two feet. Then finally to standing on one leg.
  - Abductor hallucis: Initiate with place/hold isometric contractions in sitting by passively moving the hallux into abduction and have the dancer isometrically hold the contraction for 3 to 5 seconds. Progress to AROM of great toe abduction in sitting; do not let the dancer substitute with the extensor hallucis longus. Next, the dancer can resist hallux abduction with the resistance of a small rubber band. Finally, the dancer will need to functionally progress AROM hallux abduction to a standing position.[16]
  - Dorsal & plantar interossei: Initiate in sitting or with feet on the wall. The dancer will squeeze and spread the toes without letting the toe IPJs flex. This can be progressed to standing on two feet, then standing on one foot.
  - Flexor hallucis brevis and flexor digitorum brevis: Initiate with seated doming, then progress to long sitting. Have the dancer long sit and the ankle in plantar flexion; extend the MTPJs while keeping the IPJs in neutral (no flexion). Next, progress to using the resistance of a Thera-Band while performing the aforementioned exercise.
  - Standing balance done barefoot. Initiate with single leg stance with eyes open, progress to eyes closed, then to uneven surfaces. To add more challenge, the dancer can do cervical rotation; upper extremity movement, such as port de bra; or lower extremity movement of the gesture leg, such as frappé or dèveloppé.

Evidence

Albisetti W, Ometti M, Pascale V, et al: Clinical evaluation and treatment of posterior impingement in dancers. *Am J Phys Med Rehabil* 88:349–354, 2009.

Nine out of twelve dancers with posterior ankle impingement in this study responded well to conservative PT to retrain the deep muscles of the foot to plantar flex the midfoot to decrease the amount of impingement occurring at the rear foot. (Level IV evidence)

Cook J, Purdam R: Is tendon pathology a continuum? A pathology model to explain the clinical presentation of load-induced tendinopathy. *Br J Sports Med* 43:409–416, 2009.

"Early tendon disrepair should be treated with load management and reduction in frequency and intensity of tendon loading. Degenerative tendinopathy treatments should stimulate cell activity, increase protein production (collagen or ground substance) and restructure the matrix are appropriate for this stage of tendinopathy." These treatments include: exercise with eccentric component, extracorporeal shock wave therapy, frictions, and ultrasound. (Level V evidence)

Cook J, Purdam R: Rehabilitation of lower limb tendinopathies. *Clin Sports Med* 22:777–789, 2003.

"Sporting participation does not guarantee intact function, as athletes are quick to develop strategies to unload painful structures. This can lead to specific unloading patterns within the kinetic chain, or can cause a general unloading pattern of the entire limb. They may consequently develop weakness in and around the symptomatic musculotendinous unit. Primary unloading is best identified by deficits in calf power and endurance, reduced capacity to squat, and loss of pelvic control."

"Biomechanical evaluation is an essential part of the clinical assessment and treatment of lower limb tendinopathies, even if there is little evidence to support this intervention. Management of this facet is designed to improve limb shock absorption or unload stressed structures."

"Improving shock absorption includes both increasing musculotendinous control of the antigravity units and increasing joint range. The ankle is the most important joint to treat, as range is easily compromised with injury and degeneration. The range of dorsiflexion is critical for Achilles [19] and patellar tendinopathy, as it allows greater range and lower rate of shock absorption in landing. Improving the range of motion of the stiff or cavus foot with mobilization or orthotics may also increase shock absorption."

"Complete tendon rehabilitation must be progressive and logical, with realistic time frames for each level. Each level will contain some eccentric contractions. The program should begin with a strength bias, progress to a power program, and finish with sport-specific load on the tendon." (Level V evidence)

Kulig K, Reischl SF, Pomrantz A, et al: Nonsurgical management of posterior tibial tendon dysfunction with orthoses and resistive exercise: A randomized controlled trial. *Phys Ther* 89(1):26–37, 2009.

In a randomized control trial examining treatment of posterior tibial tendon dysfunction, the group that used orthoses wear, stretching, and eccentric progressive resistive exercise demonstrated the most improvement in each subcategory (VAS, 5-minute walk test, and Foot Functional Index), when compared to other groups (orthoses wear, and concentric strengthening program along with orthoses wear). (Level II evidence)

Molnar M, Bornstein R, Hartog M, et al: Dance medicine: Strategies for the prevention and care of injuries to dancers. Foot and ankle injuries in the dancer: Examination and treatment strategies. Orthopaedic Section American Physical Therapy Association. *Independent Study Course* 18.3.5:18–19, 2008.

Expert clinical knowledge demonstrates that muscle imbalances can contribute to joint restrictions at the proximal fibula/tibia joint that warrant joint mobilizations. Clinical experts recommend taping to reduce excess load on the FHL tendon during pedestrian activities such as walking. (Level V evidence)

Pettman E: *North American Institute of Manual Therapy course manual 610—Intermediate Lower Quadrant*. Berrien Springs, MI, 2009, Lecture at Andrews University.

Talar swing test is used to determine if the talocrural joint is restricted in a posterior glide. If the joint glide is restricted, the test continues to help determine if the joint is restricted because of tight gastrocnemius, capsular tightness, or an intraarticular joint restriction, such as a loose body. (Level V Evidence)

Rees J, Wilson A, Wolman R: Current concepts in the management of tendon disorders. *Rheumatology* 45:508–521, 2006.

There are several manual therapies popular in the treatment of tendon disorders, the two most common being friction massage and soft tissue mobilization. These two are used often clinically, but there is not strong evidence in literature although it is cited that is can reduce pain. Except for eccentric training, physical therapies, strength deficits, inflexibility, and improper equipment had not been studied in a controlled and prospective manner with regard to tendon disorders. (Level III evidence)

Simpson M, Howard T: Tendinopathies of the foot and ankle. *Am Fam Physician* 80(10):1107–1114, 2009.

"A history of functional ankle instability may be present and directly related to the impingement syndrome initiation. Functional instability, as described by Maffulli and Ferran, consists of impaired proprioception, neuromuscular control deficits, postural control difficulty, and strength deficits." (Level III evidence)

Sussmilch-Leitch S, Collins N, Bialocerkowski A, et al: Physical therapies for Achilles tendinopathy: Systematic review and meta-analysis. *J Foot Ankle Res* 5:15, 2012.

"Systematic review of physical therapies for Achilles tendinopathy to perform meta-analyses and evaluate the methodological quality of included studies. Findings from individual randomized control trials support the use of eccentric exercise in the management of Achilles tendinopathy, with pooled data suggesting additional benefits using laser therapy as an adjunct intervention, and similar outcomes when shock wave therapy is utilized as an alternative to eccentric exercise."

"Sufficient evidence is lacking to enable recommendation of night splints and heel braces as a management option for Achilles tendinopathy." (Level II evidence)

Tan S, Chan O: Achilles and patellar tendinopathy: Current understanding of pathophysiology and management. *Disabil Rehabil* 30(20–22):1608–1615, 2008.

Twelve-week eccentric loading programs have shown favorable results in multiple studies both at the physiological level as well as the functional level of an athlete. (Level III evidence)

Multiple-Choice Questions

QUESTION 1. Where will a dancer have pain when presenting with FHL tendinosis?

A. Lateral ankle
B. Medial ankle
C. Anterior ankle
D. Lateral toes

QUESTION 2. In the first phase of rehabilitation of FHL tendinosis and ankle impingement what should the dancer be doing in dance class?

A. Full class including pointe work
B. Full class except pointe work
C. Flat ballet barre
D. No dancing

QUESTION 3. What ROM is most painful and limited when presenting with FHL tendinosis and ankle impingement?

A. Plantar flexion
B. Dorsiflexion
C. Forefoot abduction (winging)
D. Forefoot adduction (sickling)

QUESTION 4. What pathologies should be ruled out when diagnosing a patient with FHL tendinosis and ankle impingement?

A. Posterior tibialis tendinopathy
B. Achilles tendinopathy
C. Tarsal tunnel syndrome
D. All of the above

QUESTION 5. When is the dancer allowed to return to rehearsal?

A. Any time the artistic director says so
B. When a full class can be completed without exacerbation
C. When the dancer can jump on one leg 25 times
D. When the dancer has full strength and good alignment

Answer Key

QUESTION 1. Correct answer: **B**. (see Introduction)

QUESTION 2. Correct answer: **D** (see Program Design/ Performance Training Program of Phase I)

QUESTION 3. Correct answer: **A** (see Introduction)

QUESTION 4. Correct answer: **D** (see sports performance testing)

QUESTION 5. Correct answer: **B** (see criteria to release to full participation

Chapter 42

Plantar Fasciitis

INTRODUCTION

Charles Christopher Stroud, MD, Erick Fountain, MPT, OMPT, and Mike Pollzzie, PT, DPT, OMPT, CSCS

Epidemiology

- Ten percent of the US population presents with heel pain at some point in their lives.
- Age: 83% are between 25 and 65 years old. Peak incidence is between 40 and 60 years old. Older athletes are more susceptible.
- Sex: Studies differ on whether there is a male or female preponderance.
- Sport: Athletes who engage in running and sports with a significant amount of impact/jumping have an increased prevalence of this condition.

Pathophysiology

Intrinsic Factors

- Increased BMI (greater than 30 kg/m^2)
- Increasing age: for example, degenerative process of plantar fascia
- Reduced ankle dorsiflexion
- Pes planus or pes cavus foot posture (both foot types have been described as associated with plantar fasciitis)
- Seronegative spondyloarthropathies

Extrinsic Factors

- Increases in training program/intensity; for example, rapid increase in weight-bearing activities
- Training errors; for example, inappropriate running technique
- Prolonged walking on hard surfaces
- Inappropriate shoes; for example, stiff, thin heel and midsole
- Increased weight-bearing activities

Traumatic Factors

- Sudden forcible load on plantar fascia (forced ankle dorsiflexion while performing pushoff maneuver) may lead to plantar fascial/disruption or injury
- Repetitive impact

Classic Pathological Findings

- Myxoid degeneration/microtears in the fascia/collagen necrosis/angiofibroblastic hyperplasia
- Thickening of plantar fascia origin (Figure 42-1)

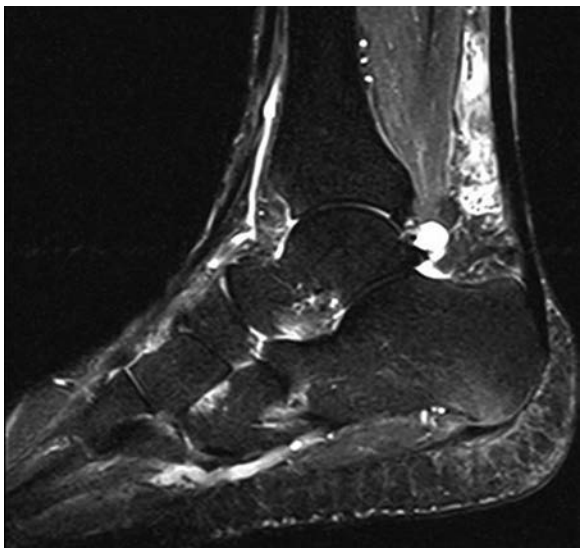

FIGURE 42-1. Sagittal T_2 MRI sequence showing the thickened insertion of the plantar fascia and mild bone marrow edema at the insertion.

FIGURE 42-2. Photograph showing the location of tenderness about the inferomedial aspect of the heel in a patient with plantar fasciitis.

Clinical Presentation

History

- Gradual onset of inferior heel pain described as a sharp stab/walking on a marble or hot poker
- Worse with first steps in morning/loosens up with walking/worse with prolonged standing/walking and toward the end of the day

Physical Examination

Abnormal Findings

- Tenderness at origin of plantar fascia (Figure 42-2)
- Contracted Achilles tendon (Figure 42-3)
- May have coexistent tenderness about the first branch of the lateral plantar nerve (Figure 42-4)
- Antalgic gait may be present.

FIGURE 42-3. Photograph demonstrating a contracted Achilles tendon. This photograph shows the Achilles tendon unable to be passively dorsiflexed to a neutral position with the knee bent.

FIGURE 42-4. Photograph showing a patient with tenderness about the first branch of the lateral plantar nerve (i.e., Baxter's nerve).

Pertinent Normal Findings

- Patient foot type may be either pes planus or pes cavus
- Lack of swelling/tenderness about the remainder of the foot

Imaging

- Imaging tests not needed in the initial workup of this condition
- If plain radiographs obtained, the presence of a calcaneal traction spur (heel spur) may or may not be present and is not the cause of this condition
- Radiographs are obtained for recalcitrant cases to rule out a calcaneal stress fracture or tumor
- Bone scan may reveal uptake at origin of plantar fascia (Figure 42-5)
- Ultrasound, if obtained, shows a thickened, hypoechoic area at the plantar fascia insertion (Figure 42-6)
- MRI, if obtained, can show thickening/increased signal about the origin of the plantar fascia (see Figure 42-1)

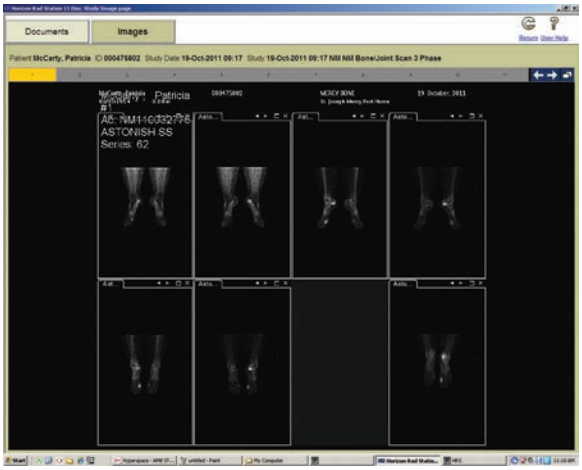

FIGURE 42-5. Bone scan showing uptake at the origin of the left plantar fascia in a patient with symptomatology.

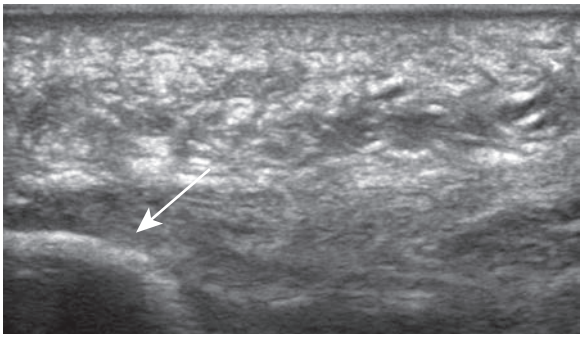

FIGURE 42-6. Ultrasound image showing a thickened hypoechoic area (*arrow*) at the origin of the plantar fascia in a patient with symptomology.

Differential Diagnosis

- Achilles tendinopathy: tenderness about the insertion of the Achilles tendon. The examiner may note the presence of thickening at the insertion and/or palpation of calcifications.
- Calcaneal apophysitis: tenderness medial and laterally in a skeletally immature patient
- Calcaneal stress fracture: pain with side-to-side compression of the heel; diffuse swelling of the heel
- Plantar fibromatosis: single or multiple nodules palpated within the central cord of the plantar fascia
- Entrapment of the first branch of the lateral plantar nerve: neuritic symptoms throughout the day, tenderness about the medial/inferior heel, positive Tinel's sign/radiating pain with percussion of the nerve
- Tarsal tunnel syndrome: neuritic symptoms, tenderness along the course of the posterior tibial nerve, positive compression/percussion sign with reproduction of symptoms
- S1 radiculopathy: subjective heel pain with no localizable symptoms; presence of radiating back pain
- Peripheral neuropathy: more global pain, history of diabetic neuropathy, decreased sensation to 5.07 monofilament testing, no localizable symptoms
- Central fat pad atrophy: tenderness about plantar central heel with attenuation of fat pad

Treatment

Nonoperative Management

- NSAIDs: not well studied as an effective modality
- Orthoses/heel cups/Inserts: no difference in custom versus off-the-shelf inserts
- Physiotherapy: Achilles/plantar fascia stretches
- Night splint: conflicting results in literature but generally accepted as effective
- Casting/walking boots: subjective improvement but not well studied
- Extracorporeal shockwave treatment: has been shown to improve symptoms in recalcitrant cases
- Corticosteroid injections: can provide short-term relief. Efficacy has not been well studied.

Guidelines for Choosing Among Nonoperative Treatments

- If severely antalgic gait: begin with short course of boot brace immobilization. If nonantalgic gait, begin with Achilles and focused plantar fascia stretches
- If no improvement after a 6-week course, consider night splint
- If no improvement after a 6-week course, consider formal physical therapy
- If no improvement after a 6-week course, consider orthotics
- If no improvement after a 6-week course, consider injection
- If no improvement after a 6-week course, consider shockwave treatment

Surgical Indications

- Recalcitrant, ongoing, unrelenting pain that has failed to improve with conservative treatment, usually 6 to 12 months

Aspects of History, Demographics, or Exam Findings That Affect Choice of Treatment

- All patients, whether athletes or not, are treated in a similar fashion
- Conservative treatment has been shown to be effective in approximately 90% of patients

Aspects of Clinical Decision Making When Surgery Is Indicated

- Failure of prolonged course of nonsurgical treatment, usually 6 to 12 months

Evidence

Berlet GC: A prospective trial of night splinting in the treatment of recalcitrant plantar fasciitis: The Ankle Dorsiflexion Dynasplint. *Orthopedics* 25:1273–1275, 2002.

The use of a night splint was noted to provide relief in patients with plantar fasciitis. (Level IV evidence)

Crawford F, Atkins D, Edwards J: Interventions for treating plantar heel pain. *Cochrane Database Syst Rev* (3):CD000416, 2000.

Differing interventions for patient with plantar fasciitis are discussed. (Level V evidence)

Davies PF: Painful heel syndrome; results of nonoperative treatment. *Foot Ankle Int* 15:531–535, 1994.

The successful results of nonoperative treatment are reviewed and discussed. (Level IV evidence)

DiGiovanni BF, et al: Plantar fascia-specific stretching exercise improves outcomes in patients with chronic plantar fasciitis: A prospective clinical trial with two-year follow-up. *J Bone Joint Surg A* 88:1775–1781, 2006.

This prospective, randomized trial showed that 52% of patients' heel pain was eliminated or improved with a plantar fascia specific program at 8 weeks versus 22% in the Achilles stretching program alone. Two-year follow-up showed no difference between the two groups. (Level I evidence)

Donley BG, et al: The efficacy of oral nonsteroidal anti-inflammatory medication (NSAID) in the treatment of plantar fasciitis: A randomized, prospective, placebo-controlled study. *Foot Ankle Int* 28:20–23, 2007.

Pain and disability scores were compared between a group treated with an NSAID vs placebo. Improved pain relief was seen in the NSAID group, but no statistical difference was noted. (Level I evidence)

Landorf KB, et al: Effectiveness of foot orthoses to treat plantar fasciitis: A randomized trial. *Arch Intern Med* 166:1305–1310, 2006.

One hundred thirty-five patients were divided into three groups (sham orthosis, off-the-shelf orthosis, and custom orthotics) and efficacy noted. No difference at 12 months was noted among the three groups. (Level I evidence)

Lemont H, Ammirati KM, Usen N: Plantar fasciitis: A degenerative process (fasciosis) without inflammation. *J Am Podiatr Med Assoc* 93:234–237, 2003.

The pathological findings in the surgical specimens of patients with plantar fasciitis are reviewed. (Level V evidence)

Odgen JA: Electrohydraulic high-energy shock-wave treatment for chronic plantar fasciitis. *J Bone Joint Surg Am* 86:2216–2228, 2004.

Seventy-seven percent of patients with chronic plantar fasciitis treated with one or more treatments of high energy shock wave had good/excellent results. (Level IV evidence)

Pfeffer G, et al: Comparison of custom and prefabricated orthoses in the initial treatment of proximal plantar fasciitis. *Foot Ankle Int* 20:214–221, 1999.

A randomized trial of 236 patients treated with various shoe inserts with a control group noted improvement in heel pain with the use of prefabricated inserts. (Level I evidence)

Powell M, et al: Effective treatment of chronic plantar fasciitis with dorsiflexion night splints: A crossover prospective randomized outcome study. *Foot Ankle Int* 19:10–18, 1998.

A randomized trial of 37 patients found that a night splint was effective in patients with chronic plantar fasciitis at 1 year follow-up. (Level I evidence)

Probe RA: Night splint treatment for plantar fasciitis. A prospective randomized study. *Clin Orthop Relat Res* 368:190–195, 1999.

The use of a night splint was noted to provide relief in patients with plantar fasciitis. (Level I evidence)

Riddle DL, Pulisic M, Pidcoe P, et al: Risk factors for plantar fasciitis: A matched case-control study. *J Bone Joint Surg Am* 85(5):872–877, 2003.

Reduced ankle dorsiflexion, obesity and work-related weight-bearing are risk factors for developing plantar fasciitis. (Level II evidence)

Multiple Choice Questions

QUESTION 1. Which of the following is one of the strategic historical features in patients with plantar fasciitis?

A. Pain at rest
B. Radiating numbness into the arch
C. Pain with the first steps in the morning
D. A contracted Achilles tendon

QUESTION 2. Which of the following is one of the strategic physical exam findings in patients with plantar fasciitis?

A. Tenderness at the inferomedial aspect of the heel
B. A positive Tinel's sign over the plantar fascia origin
C. Swelling about the medial heel
D. A unilateral pes planus foot deformity

QUESTION 3. What are the histological findings noted in the surgical specimens in patients with plantar fasciitis?

A. Edema
B. Microfibrillar tearing
C. Tendon thickening
D. Myxoid degeneration
E. All of the above

QUESTION 4. Which of the following is not in the differential diagnoses in the patients who presents with heel pain?

A. Calcaneal stress fracture
B. Radiculopathy
C. Posterior ankle impingement
D. Tarsal tunnel syndrome

QUESTION 5. Which of the following is not one of the conservative treatment options in a patient with plantar fasciitis?

A. Boot brace immobilization
B. Sclerosing alcohol injections
C. Formal course of physiotherapy
D. Specific plantar fascia stretching exercises

Answer Key

QUESTION 1. Correct answer: **C** (see Clinical Presentation)

QUESTION 2. Correct answer: **A** (see Clinical Presentation)

QUESTION 3. Correct answer: **E** (see Pathophysiology)

QUESTION 4. Correct answer: **C** (see Differential Diagnosis)

QUESTION 5. Correct answer: **B** (see Treatment)

NONOPERATIVE REHABILITATION OF PLANTAR FASCIITIS

Charles Christopher Stroud, MD, Erick Fountain, MPT, OMPT, and Mike Pollzzie, PT, DPT, OMPT, CSCS

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- Protected weight bearing until normal gait
- Pain reduction and restoration of motion
- Progressive strengthening and functional assessment
- Return to specific functional demands or sport-specific activity level

Phase I (weeks 0 to 2)

Protection

- If the patient has a continuous antalgic gait, a boot brace with or without crutches, depending on the level of pain, is supplied. If the gait is nonantalgic, no boot brace is needed.

Management of Pain and Swelling

- Ice and/or heat, NSAIDs taken as needed, protected weight bearing if necessary.

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- If the patient is in a boot, then gentle, progressive active range of motion of the knee, ankle and foot (out of boot) is performed. If no boot, than begin Achilles and plantar fascia specific stretches (Figure 42-7).

Other Therapeutic Exercises

- Patient can continue with general upper body workouts.
- Patient can continue with general core strengthening.
- Patient can continue with general hip/thigh exercises.

Activation of Primary Muscles Involved

- Patients should perform the preceding to the point that they "feel" the stretch and not pain.

Milestones for Progression to the Next Phase

- Achieve nonantalgic gait with or without protective walking boot.
- Discontinue crutches if used.
- Wean out of walking boot if used.

FIGURE 42-7. A, Stretch of the gastroc-soleus complex with a towel. **B,** Stretch of gastroc-soleus complex against a wall with foot pointed forward and knee straight (affected leg back). **C,** Stretch of gastroc-soleus complex against the wall with foot pointed forward and knee bent (affected leg is forward). **D,** Stretch of gastroc-soleus complex using a stair for a more aggressive stretch. **E,** Stretch of the plantar fascia. Note that the knee is bent and one arm is used for the stretch and the other finger is used to palpate the plantar fascia. Each stretch should be performed to a count of 10, three sets and three times per day.

Phase II (weeks 2 to 4)

Management of Pain and Swelling

- As-needed usage of NSAIDs
- The use of IFC, TENS unit, iontophoresis, contrast baths can be used if enrolled in formal physical therapy.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- If a formal physical therapy program is used, than talocrural/subtalar glide maneuvers and subtalar joint distraction can be used. Efficacy not well documented

Soft Tissue Techniques

- Deep soft tissue massage techniques can be used by the therapist, although their efficacy not well documented.

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Specific weight-bearing and non–weight-bearing stretches of the gastroc-soleus complex and of the plantar fascia as noted in the preceding section (see Figure 42-7).

Other Therapeutic Exercises

- Continue with patients regular conditioning exercises
- Add an aggressive and progressive program of hip/core/thigh strengthening exercises; for example, step-ups and step downs, box touches, toe touches, forward/backward/side monster walks, bridge exercises, assisted to full body split squats (Figure 42-8).

Activation of Primary Muscles Involved

- Progressive motion/stretching of the gastroc-soleus complex and great/lesser toe dorsiflexors and plantar flexors. Four-way resistance band exercises of the ankle are used (Figure 42-9).

Sensorimotor Exercises

- Single/double leg balance exercises, progressing from even to uneven surfaces. These exercises can be performed with the use of a DynaDisc, BAPS board, or BOSU (Figure 42-10; see also Figure 42-19 in the next section).

Open and Closed Kinetic Chain Exercises

- CKC exercises (single/double leg split squat) are performed in the PT facility (Figure 42-11), whereas OKC (band exercises) are performed via a home exercise program.

Techniques to Increase Muscle Strength, Power, and Endurance

- The preceding exercises are performed progressing from lower to high repetitions while increasing load/resistance over ensuing weeks.

Neuromuscular Dynamic Stability Exercises

- Core ball exercises, single leg balance exercises, rotational exercises (Figure 42-12).

Milestones for Progression to the Next Phase

- Normal gait, no limp
- Normal knee/ankle range of motion
- Minimal pain with regular daily activities

Phase III (weeks 4 to 8)

Protection

- Orthotic usage can be considered at this point.
- Low-dye taping can be applied by the therapist to control pain and provide stability to the foot.

TIMELINE 42-1: **Nonoperative Rehabilitation of Plantar Fasciitis**

PHASE I (weeks 0 to 2)	PHASE II (weeks 2 to 4)

• Boot if patient limping
• PT modalities
• Goal is to wean out of boot and achieve normal gait
	• PT modalities
	• Talocrural/subtalar glide, subtalar joint distraction
	• Deep soft tissue massage
	• Gastroc-soleus stretches
	• Progressive core strengthening, including:
	  • Step-ups/step-downs
	  • Box touches, toe touches
	  • Monster walks
	  • Bridge exercises
	• Assisted split squats progressing to full body split squats
	• Four-way resistance band exercises for the ankle
	• Single/double leg balance exercises progressing from even to uneven surfaces
	• Add DynaDisc/BAPS board or BOSU
	• Core ball/single leg balance/rotational exercises

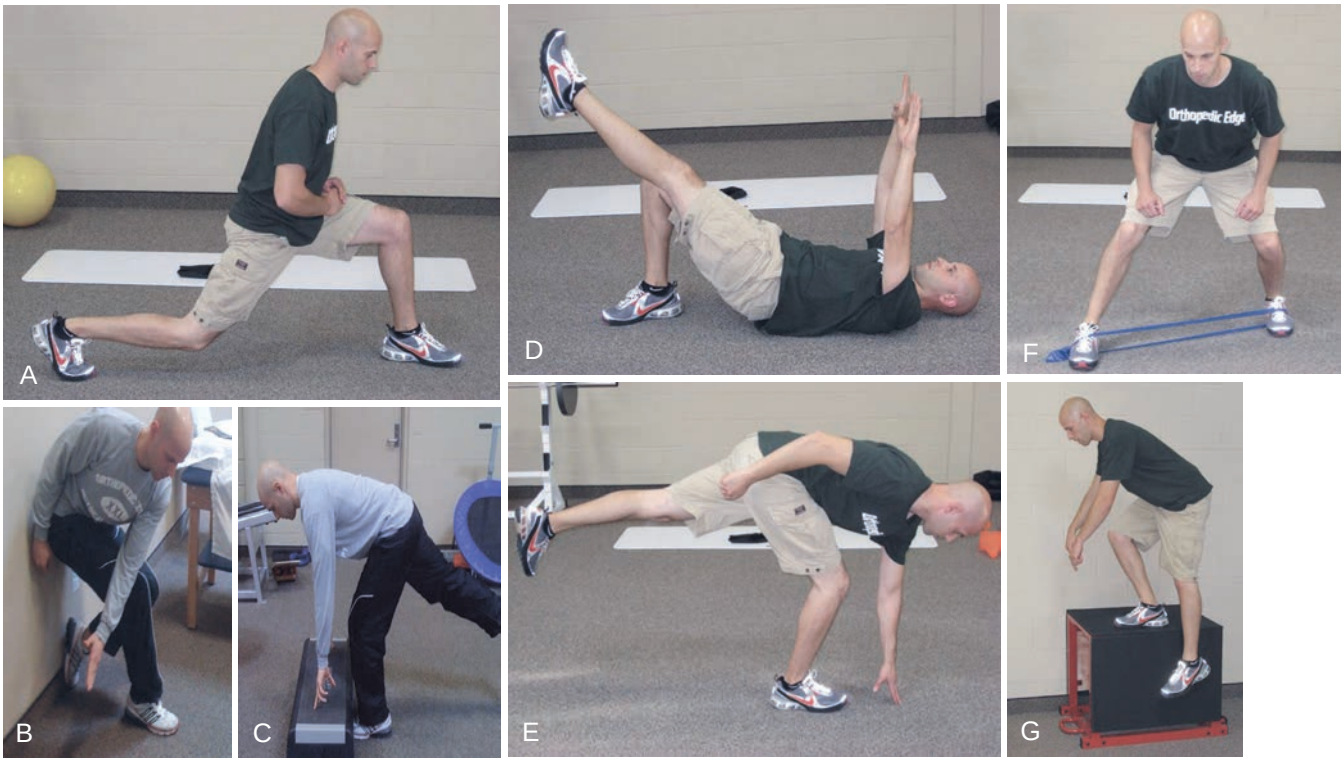

FIGURE 42-8. A, Split squat exercise. **B,** Assisted split squat crossover. **C,** Box touches. **D,** Bridge exercise. **E,** Toe touch. **F,** Monster walk with band. **G,** Step up/down.

Management of Pain and Swelling

- NSAIDs as needed

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- As in the preceding

Soft Tissue Techniques

- As in the preceding

Stretching and Flexibility Techniques for the Musculotendinous Unit

- As in the preceding
- Formal physical therapy, if not used previously, can be prescribed at this point.
- Also, the use of a night splint can also be considered at this point.

Other Therapeutic Exercises

- Progressively increasing the repetitions/load in the following exercises, as noted in previous section: step-ups/

TIMELINE 42-1: **Nonoperative Rehabilitation of Plantar Fasciitis** (Continued)

PHASE III (weeks 4 to 8)	PHASE IV (weeks 8 to 12)
• Orthotics/low dye taping • PT modalities as needed • Aggressive gastroc/plantar fascia stretches • Consider night splint • Triplanar foot/ankle proprioception exercises • Multidirectional slide board exercises • Slow hopping/gentle cutting • Agility ladder drills • Box jumps • Slow treadmill walking/jogging • Progress cardiovascular fitness • As above but increase repetitions/loading	• As above • Increase duration/frequency of impact/running time • By 3 months, should have athlete ready for regular routine

FIGURE 42-9. Four-way resistance exercises of the ankle using a band are demonstrated. Resisted eversion is noted here. Each exercise should be performed 10 times, three sets and two times per day.

FIGURE 42-10. Double leg balance exercise on the BOSU is shown.

FIGURE 42-11. Split squat exercise is shown.

FIGURE 42-12. Dynamic stability exercises (i.e., side reach with a weight).

step-downs, plank exercises, box touches, toe touches, forward/backward/side monster walks, bridge exercises

Activation of Primary Muscles Involved

- Continue stretches as noted in previous section. Single leg training continues: assisted split squats to full body weight.

Sensorimotor Exercises

- Single/double leg balance exercises continue as noted in previous section.
- Progress from an even to an uneven surface using a DynaDisc, BAPS board. and BOSU.
- Triplanar foot/ankle proprioceptive exercises, multidirectional slide board exercises used in both a static and dynamic way.

Open and Closed Kinetic Chain Exercises

- As in the preceding

Techniques to Increase Muscle Strength, Power, and Endurance

- Increased repetitions of strengthening exercises, calf raises

Plyometrics

- Begin slow hopping/gentle cutting/agility ladder drills/box jumps (Figure 42-13).

Functional Exercises

- Slow treadmill walking/jogging for limited time

FIGURE 42-13. Demonstrating double leg box jumps for plyometric exercises.

Sport-Specific Exercises

- Begin treadmill for runners/karaoke for team sports/elliptical for general cardiovascular fitness.

Milestones for Progression to the Next Phase

- Strength nearly equal to contralateral leg; for example, ability to perform
  - A single leg calf raise through at least 80% of ROM in weight bearing
  - A single leg squat on involved leg performed at 85% of total reps of uninvolved leg
  - A open chain manual muscle testing demonstrates 5/5 strength for quads, hams, and gastroc/soleus complex.
- The ROM for the calf raise is based on observation of the involved and uninvolved LE. The SL squat is performed first on the uninvolved LE, counting the max reps to failure and then reproduced on the involved LE.
- We are evaluating the patient's ability to perform selected movement tests compared with the healthy LE. There are several ways to measure and evaluate and these are just a few of most simple ways.
- Pain limited to end of workout.

Phase III (weeks 8 to 12)

Management of Pain and Swelling

- If the pain continues, the physician will consider the use of a one- or two-time corticosteroid injection around the origin of the plantar fascia.
- Approximately a 1-month interval should be allowed before a repeat injection is performed to allow for soft tissue healing.
- At the end of the 3-month period of treatment, if pain continues, the patient could consider shockwave treatment to the plantar fascia, if available.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- As in the preceding

Soft Tissue Techniques

- As in the preceding

Stretching and Flexibility Techniques for the Musculotendinous Unit

- As in the preceding and regular Achilles/plantar fascia stretches

Other Therapeutic Exercises

- As in the preceding

Activation of Primary Muscles Involved

- As in the preceding

Sensorimotor Exercises

- As in the preceding

Open and Closed Kinetic Chain Exercises

- As in the preceding

Techniques to Increase Muscle Strength, Power, and Endurance

- As in the preceding. The patient will perform single leg squats with rotational reach with subsequent hop; jumping activities; calf raises with maximal ankle dorsiflexion; step downs with opposite leg reach in all planes.

Neuromuscular Dynamic Stability Exercises

- As in the preceding

Plyometrics

- As in the preceding

Functional Exercises

- Begin increasing duration and/or frequency of impact/running time. Functional exercises when seen in the PT clinic depend on patient's symptomatology at presentation. If symptomatic, progress with lesser weight-bearing exercises such as multiplane balance training in double leg stance, such as step ups, partial WB full ROM calf raises, weight shifting in the frontal plane with band resistance, leg press, stationary bike and elliptical machine use. If minimal patient symptoms, then progress to single leg training with these exercises.

Sport-Specific Exercises

- Begin light workouts in the patients' specific activity of choice. During this phase of rehabilitation, we start submaximal sport specific training. We go through periods of training and re-assessment within a session to make sure the patient is tolerating the training. The patient performs the exercises at a slower speed to ensure correct movement patterns and tolerance to activity. In whichever sport the patient is involved, we often recommend a 50% reduction in the speed and 50% in the load of that specific sport.

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- All goals achieved, none to minimal pain about the heel noted.
- The patient demonstrates the ability to control motion through the sagittal, frontal, and transverse planes at slower speeds. The patient should demonstrate no pain with multijoint movement testing. Specifically the patient should be able to:
  - Perform a single leg calf raise from a full dorsiflexed ankle position in weight bearing.
  - Perform step lunges and hopping in different directions.
  - Perform or use the agility ladder for four to five cycles/back and forth at moderate speed.
- The therapist looks for full forefoot weight bearing during these exercises as a signal to progress.

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention

- Failure to obtain patient activity goals by 3 months of intensive treatment or 6 to 9 months of symptoms
- Ongoing pain that limits desired activity

Tips and Guidelines for Transitioning to Performance Enhancement

- Begin progressive sport specific or running program. Progress every other day 10 minutes or 10% mileage increase per week.

Performance Enhancement and Beyond Rehabilitation: Training/Trainer and Optimization of Athletic Performance

- Regular stretching
- Counseled regarding appropriate footwear
- Counseled regarding appropriate training techniques

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Able to sprint 40 yards without pain
- Able to perform cutting/twisting maneuvers. There are no specific guidelines driving these tests. However the tests that the therapist uses will try to closely replicate game situations; for example, cone drills, agility ladder drills, etc.
- Able to perform single leg hop 10 repetitions
- Quick stops/pivots/turning maneuvers
- Interval training: jog for 3 minutes, run/sprint for 30 seconds, walk for 1 minute

Evidence

Batt ME: Plantar fasciitis: A prospective randomized clinical trial of the tension night splint. *Clin J Sport Med* 6:158–162, 1996.

A good outcome was noted in patients treated with 9 to 12 weeks of night splint usage. (Level II evidence)

DiGiovanni BF: Tissue-specific plantar fascia-stretching exercise enhances outcomes in patient with chronic heel pain. A prospective, randomized study. *J Bone Joint Surg Am* 85-A:1270–1277, 2003.

The patient group that performed specific plantar fascia stretches was noted to have a significant reduction or elimination in pain compared with those with calf stretches alone. (Level I evidence)

Kudo P: Randomized, placebo-controlled, double-blind clinical trial evaluating the treatment of plantar fasciitis with an extracorporeal shockwave therapy (ESWT) device: A North American confirmatory study. *J Orthop Res* 24:115–123, 2006.

A statistically significant improvement in symptoms was noted at 3 months in the group that received one high-energy shock wave treatment. (Level I evidence)

Landorf KB: Effectiveness of foot orthoses to treat plantar fasciitis: A randomized trial. *Arch Intern Med* 166:1305–1310, 2006.

This blinded, randomized trial noted that of 136 patients who were treated with either a sham orthosis, a prefabricated orthosis or a custom orthosis, the groups treated with the prefabricated and custom orthoses produced short-term relief of symptoms that than was not significant after 1 year. (Level I evidence)

Pfeffer G: Comparison of custom and prefabricated orthoses in the initial treatment of proximal plantar fasciitis. *Foot Ankle Int* 20:214–221, 1999.

The groups treated with the prefabricated inserts and stretching had better outcomes than the custom orthotic group or stretching group along at short term follow-up. (Level III evidence)

Porter D: The effects of duration and frequency of Achilles tendon stretching on dorsiflexion and outcome in painful heel syndrome: A randomized, blinded, control study. *Foot Ankle Int* 23:619–624, 2002.

Patients randomized to either a sustained stretch or an intermittent stretch were noted to have an increase in ankle

dorsiflexion which correlated with a reduction in pain versus the control group. (Level II evidence)

Powell M: Effective treatment of chronic plantar fasciitis with dorsiflexion night splints: A crossover prospective randomized outcome study. *Foot Ankle Int* 19:10–18, 1998.

Eighty-eight percent of 37 patients were noted to have improvement in their chronic plantar fascial symptoms when worn for 1 month. (Level III evidence)

Rompe JD: Shock wave application for chronic plantar fasciitis in running athletes: A prospective, randomized, placebo-controlled trial. *Am J Sports Med* 31:268–275, 2003.

Morning pain was reduced in the treatment group at 6 and 12 months with 3 treatments of low energy shock wave. (Level I evidence)

Roos E: Foot orthoses for the treatment of plantar fasciitis. *Foot Ankle Int* 27:606–611, 2006.

Comparing the use of foot orthoses versus foot orthoses plus night splint or night splint only, the authors noted improvement in pain at 1 year follow-up in all groups. (Level II evidence)

Tisdel CL: Chronic plantar heel pain: Treatment with a short leg walking cast. *Foot Ankle Int* 17:41–42, 1996.

A short trial of a walking boot was noted to reduce symptoms of plantar fasciitis. (Level IV evidence)

Wang CJ: Long-term results of extracorporeal shockwave treatment for plantar fasciitis. *Am J Sports Med* 34:592–596, 2006.

Eighty-three percent of patients who received high-energy shockwave treatment noted good/excellent results at 72-month follow-up. (Level III evidence)

Multiple Choice Questions

QUESTION 1. Stretching exercises of which structure(s) typically resolves plantar heel pain?

A. Achilles tendon
B. Gastrocnemius/soleus
C. Plantar fascia
D. All of the above

QUESTION 2. Surgical treatment is generally considered after approximately ___ months of patient symptoms?

A. 1
B. 3
C. 6 to 9
D. 12

QUESTION 3. An aggressive core strengthening program is initiated in which phase of the nonoperative treatment of patient with plantar fasciitis?

A. Phase I
B. Phase II
C. Phase III
D. Phase IV

QUESTION 4. The use of a prefabricated, or off-the-shelf, insert has been shown to be as effective if not more effective than a custom orthotic.

A. True
B. False

QUESTION 5. Use of all of the following has been shown in the literature to be effective in the treatment of patient with plantar fasciitis, except one.

A. Night splint
B. Plantar fascia specific stretches
C. Prefabricated inserts
D. Distraction (manual) therapy

Answer Key

QUESTION 1. Correct answer: **D** (see Phase I)

QUESTION 2. Correct answer: **C** (see Phase IV)

QUESTION 3. Correct answer: **B** (see Phase II)

QUESTION 4. Correct answer: **A** (see Phase III)

QUESTION 5. Correct answer: **D** (see Phase II)

POSTOPERATIVE REHABILITATION AFTER PLANTAR FASCIITIS SURGERY

Charles Christopher Stroud, MD, Erick Fountain, MPT, OMPT, and Mike Pollzzie, PT, DPT, OMPT, CSCS

Indications for Surgical Treatment

- Persistent heel pain unresponsive to nonsurgical treatment over a 6- to 9-month period
- Pain that limits the desired athletic activity as well as activities of daily living
- Nonoperative treatment is generally successful in over 90% of patients and is recommended for a minimum of 6 months.
- A gastrocnemius release is considered in those patients with a demonstrable tight Gastrocnemius (i.e., a positive Silverskold test).

- These recommendations apply to both athletes and nonathletes

Brief Summary of Surgical Treatment

Major Surgical Steps

- Regional or local anesthesia; patient in semilateral position with bump/bean bag placed under the unaffected hip
- Calf tourniquet use is encouraged.
- Skin incision followed by dissection down to abductor hallucis fascia
- If just performing a plantar fascial release, dissect to confluence of plantar fascia and abductor hallucis (AH) fascia
- Palpate with a freer elevator the width/thickness of plantar fascia as it inserts on the calcaneus
- If performing a release of the first branch of the lateral plantar nerve, release AH fascia, retract muscle belly inferiorly and release deep fascia. Retract muscle belly superiorly and complete deep AH fascia release.
- Excise, medially to laterally, approximately 60% of the thickened plantar fascia.
- Gastrocnemius release is controversial but can be considered in individuals with a demonstrable gastroc equinus contracture and is performed now (see appropriate chapter for technique).
- Apply a padded compression dressing (if just plantar fascia release) or posterior splint in neutral position (if gastrocnemius release performed)

Factors That May Affect Rehabilitation

Anesthetic

- Modalities and limb elevation are crucial postoperatively to limit hematoma formation.

Surgical

- If gastrocnemius release performed, will need to aggressively address lower leg strengthening postoperatively

Other Surgical Techniques and Options

- The addition of a gastrocnemius release can be a useful adjunct in operative treatment.
- The patient will require more focused postoperative treatment of the lower leg in addition to the foot.

Before Surgery: Overview of Goals, Milestones, and Guidelines[1]

GUIDING PRINCIPLES OF POSTOPERATIVE REHABILITATION

- Understand the significant weight bearing forces that act on the foot while the tissues are healing
- Limit limb swelling and hematoma formation in the immediate postoperative period
- Protected weight bearing in a walking boot in the subacute postoperative period
- A progressive program of weight bearing, stretching and strengthening follows

Phase I (days 0 to 14): Immediate Postoperative Period

Clinical Pearl

Patient will perform his or her own application of ice and perform gentle range of motion exercises of the hip/knee and ankle during this phase.

Goals

- Limit activity related swelling/hematoma formation
- Progressive mobilization of the lower leg
- Transition into a boot brace
- Progressive weight bearing as tolerated (if not in a splint)

[1]*Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.*

TIMELINE 42-2: **Postsurgical Rehabilitation after Plantar Fasciitis Surgery**

PHASE I (weeks 1 to 2)	PHASE II (weeks 2 to 6)
• In boot • Ice prn • AAROM/ AROM in all planes • Self-stretching for edema reduction and pain control	• WBAT in boot, progressing to OOB as symptoms allow. • PT modalities • Restore normal joint mobility at the TC and ST joints • Functional massage to normalize soft tissue mobility in the calf and posterior leg • Begin more aggressive calf stretching in WB • Progress AROM into RROM in OKC • Begin WB strength training program, progressing to higher level functional training in all planes of motion. • Maximize efficiency of gait pattern • Teach pt self-mobilizations for control of isolated PF pain • Advance with CKC strength, balance and proprioceptive training.

Protection

- Crutches are used until the first postoperative visit.
- Patient can be weight bearing as tolerated with crutches if just dressing used, non–weight bearing if a splint is applied.

Management of Pain and Swelling

For Pain

- Regional/local anesthesia reduces immediate postoperative pain
- Oral narcotic pain medication

For Swelling

- Limb elevation, gentle ankle range of motion, if not in a splint

Techniques for Progressive Increase in Range of Motion

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Stretching/flexibility techniques for the musculotendinous unit
- Gentle active range of motion of the knee, ankle, and subtalar joint

Other Therapeutic Exercises

- Begin upper body, core exercises, hip and thigh strengthening (i.e., straight leg raises)

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Gentle, progressive, active range of motion exercises of the knee, ankle, and subtalar joint, emphasizing full extension of the knee

Milestones for Progression to the Next Phase

- Patients should have at least 0° of ankle dorsiflexion and at least 30° of plantarflexion and a decreasing level of pain

Phase II (postoperative weeks 2 to 6)

Clinical Pearls

- This is the phase in which normal gait and range of motion is achieved.
- Patients can generally progress with their own home program or can be enrolled in formal physical therapy at this point.
- The overriding principle during this phase of treatment is to create and control load and force during weight bearing on the affected leg.
- Also, the patient will begin functional training as early as possible.
- Soft tissue mobilization is begun immediately.

Goals

- Further reduce pain/swelling
- Achieve a nonantalgic gait pattern
- Achieve full range of motion of ankle and hindfoot
- Initiate plantarflexion and calf strengthening

Protection

- Boot brace used until normal gait pattern

Management of Pain and Swelling

For Pain

- Oral narcotic/NSAID medication, IFC, TENS unit, iontophoresis, ice
- Begin warm water immersion or contrast baths depending on patient preference

TIMELINE 42-2: **Postsurgical Rehabilitation after Plantar Fasciitis Surgery** (Continued)

PHASE III (weeks 6 to 10)	PHASE IV (weeks 10 to 14)	PHASE V (weeks 14 to 24)
• Normal gait pattern with good push off noted at toe off phase of gait • Manual therapy prn: higher level joint stretches to resolve lingering jt ROM loss • Functional massage to control c/o pain and residual edema • Advance WB calf stretching to include full WB plantar fascia stretching • Progress exercises from above phase by advancing reps, then speed, then load • Functional training will include kettle bells, core and medicine balls • Focus moves from double leg to single leg stance training • Plyometric and hopping exercises can be initiated	• Normal gait pattern • Normal AROM/PROM of the involved foot and ankle • Edema should be resolved • Continue with calf and plantar fascia stretching/ self-mobs as needed • Modalities prn for management of any lingering ST soreness • High level core and balance training in WB • Emphasis on speed and performance recovery • Aggressive focus on gastroc strength recovery if gastroc release was performed • Initiate sport-specific training and jogging • Goal to achieve calf strength equal to 80–90% of uninvolved leg • Noticeable gastroc girth recovery	• Return to sport • Full function without residual pain or ROM loss • Ongoing lower extremity stretching, as needed, to maintain proper mechanics with functional training and exercise program

FIGURE 42-14. Photo demonstrating soft tissue mobilization technique to be administered by the patient at home.

FIGURE 42-16. Photo of assisted split squats using the TRX training system.

For Swelling

- Range of motion, ice, compression stockings. Patients will begin a home self-administered soft tissue mobilization/stretching program to the plantar fascia (Figure 42-14)

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Talocrural and subtalar joint mobilization
- There is limited evidence to support the use of manual therapy techniques in the treatment plan, but these techniques are often used.

Soft Tissue Techniques

- Functional massage of plantar fascia and gastroc-soleus complex in prone position; for example, soft tissue mobilization

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Patient or therapist aggressively begins calf stretches, and great and lesser toe stretches. This includes:
- PWB calf stretches (bilateral stance thus splitting body weight
- Active patient standing calf stretch with knee straight and bent (Figure 42-15*A*,*B*)
- Great and lesser toe dorsiflexion exercises
- Dynamic stretching while in boot (hamstring/hip rotators, including hip flexors/extensors/groin

Other Therapeutic Exercises

- Core/hip/leg strengthening continues: step-ups and step-downs, box touches, toe touches, forward/backward monster walks, side walks, bridge exercises, and single leg training to restore control of WB and hip stability
- Using TRX training system, progress from assisted split squats to full body weight over a 4-week period (Figure 42-16).
- For hip stability, use triplanar foot/ankle proprioceptive exercises on uninvolved leg; that is, multidirectional slide board exercises as well as static/dynamic slide board exercises (Figure 42-17*A*,*B*).
- Abdominal training for motion control during gait, all WB on involved limb (plank exercises) while in boot early and progress to out of boot (Figure 42-18).

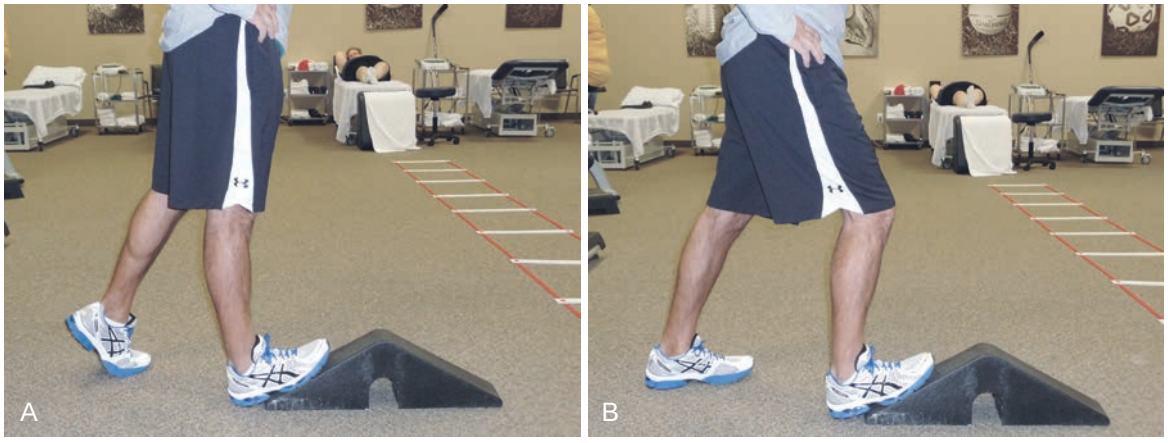

FIGURE 42-15. A,B, Photo demonstrating a partial weight-bearing calf stretch used while out of the boot, with knee extended and flexed.

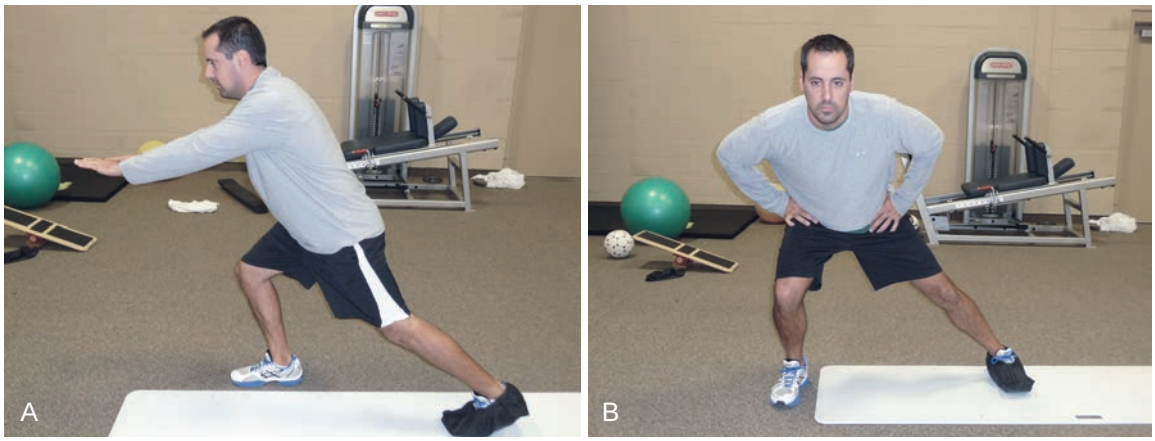

FIGURE 42-17. Photo demonstrating hip and core stabilization exercises using a multidirectional slide board, here both straight ahead (**A**) and lateral (**B**).

- Elliptical machine, both in/and out of boot, for general cardiovascular benefit.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Immediate and progressive motion of the gastrocnemius/soleus complex and great/lesser toe plantar flexors and dorsiflexors. Four-way resistance band exercises of ankle used.

Sensorimotor Exercises

- Single and double leg balance exercises (even progressing to uneven surfaces), DynaDisc, BAPS board, BOSU (Figure 42-19)

Open and Closed Kinetic Chain Exercises

- CKC exercises while in PT facility; that is, single/double leg, split stance
- Home exercises include open chain (band exercises) for hip, leg, and foot/ankle.

FIGURE 42-18. Photo demonstrating plank exercises (while patient is in or out of boot) used for abdominal training during this phase of recovery.

Techniques to Increase Muscle Strength, Power, and Endurance

- Check for proper muscle firing (normal gait mechanics), working on proper motion control of hip/knee/ankle during gait. Work on increasing from low load, low reps to higher load and repetitions.

Neuromuscular Dynamic Stability Exercises

- See Sensorimotor section.
- Weight-shifting evaluation: proper gait/pivoting mechanics, proper control of pronation/supination; that is, core ball exercises. Progress to single leg balance (i.e., therapeutic exercise section) and rotational exercises all with the goal of creating and controlling force (Figure 42-20*A*–*C*)

FIGURE 42-19. Photo demonstrating double leg balance exercises on BOSU, DynaDisc, or BAPS board.

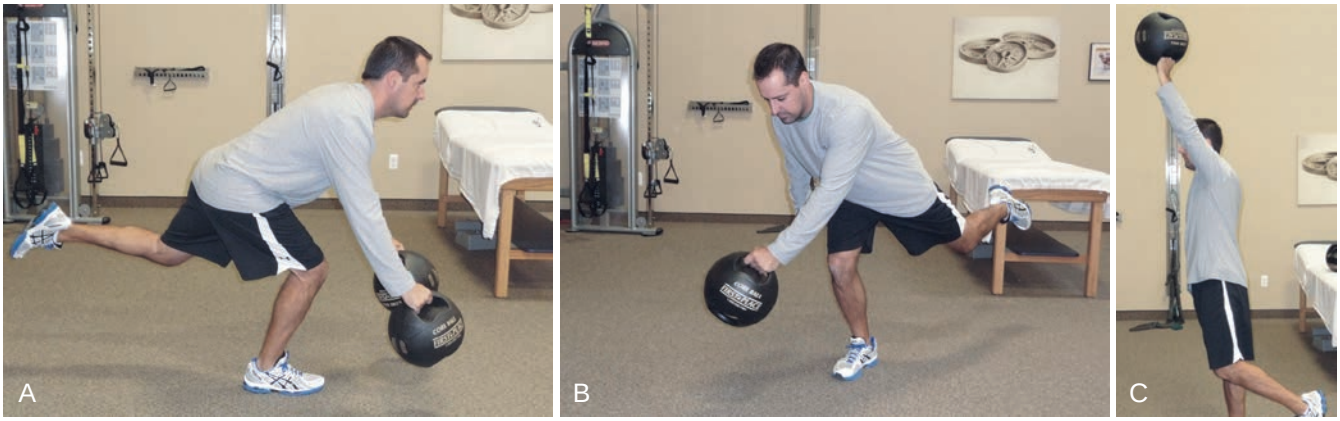

FIGURE 42-20. A-C, Photo of core ball exercises used to maximize proper control of lower extremity with forward, rotational, and upward reach.

Functional Exercises

- Lower extremity motion control exercises, progression and load, proper gait mechanics. Achieve normal gait, which requires 10° of ankle dorsiflexion.

Milestones for Progression to the Next Phase

- Pain controlled: no increase in pain with performance of above program, no lasting pain (greater than 24 to 48 hours post PT).
- Proper gait mechanics, restoration of motion

Phase III (postoperative weeks 6 to 10)

Clinical Pearls

- This is the phase in which strength gains are most noted.
- Progress load/speed of activity and repetitions of involved leg
- Constant testing/retesting of the soft tissues, joint mobility and function in order to advance treatment plan

Goals

- Demonstrate isometric control of ankle muscle in plantarflexion (i.e., adequate push off during toe-off portion of gait)
- Greater than 50% strength/power production of uninvolved leg as measured by number of maximum repetitions compared with contralateral leg

Protection

- Supportive taping (PT or patient) as needed. Calcaneal or low-dye taping may provide short-term relief of symptoms.

Management of Pain and Swelling

For Pain

- Switch to anti-inflammatory pain medication taken as needed.

For Swelling

- Edema reducing soft tissue massage as needed

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- ROM should be normal; however more aggressive talocrural ROM, emphasizing the posterior ankle and subtalar joint.
- Long axis talocalcaneal traction, all performed to resolve residual joint limitations

Soft Tissue Techniques

- Functional massage continued

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Full WB and full range stretch (single leg calf stretch, knee bent/flexed), elevate great toe MTP joint for additional stretch with and w/o WB

Other Therapeutic Exercises

- Same as in the preceding section but without boot

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- If gastrocnemius release performed, aggressive plantarflexion exercises with Thera-Bands, isometric plantar flexion exercises in weight-bearing position. Same as in the preceding phase but emphasizing increased speed/repetitions.

FIGURE 42-21. Photo demonstrating single leg balance with the use of kettle bells or medicine balls.

FIGURE 42-23. Photo demonstrating Plyo-box jump exercises.

Sensorimotor Exercises

- Emphasis on single leg balance, such as kettle bells and weighted medicine balls.
- Single leg dead lifts, single leg squats, slide board, lunges, split squat lunging (Figure 42-21)
- Triplanar lunges

Open and Closed Kinetic Chain Exercises

- Same as previous section

Techniques to Increase Muscle Strength, Power, and Endurance

- Increasing repetitions, maximizing ROM of hip/knee/ankle, increasing load
- If 15 to 20 repetitions can be achieved w/o fatiguing, then progress and increase load

Neuromuscular Dynamic Stability Exercises

- Teach patterns of movement using agility drills (use agility ladder): double leg lateral hopping (Figure 42-22).
- Progress from walking to trotting to quick movements.

Plyometrics

- Begin plyometric exercises: Bounding exercises, agility ladder, Plyo-box jumps (Figure 42-23)
- Teach proper landing techniques.
- Teach to control lower extremity pronation/supination

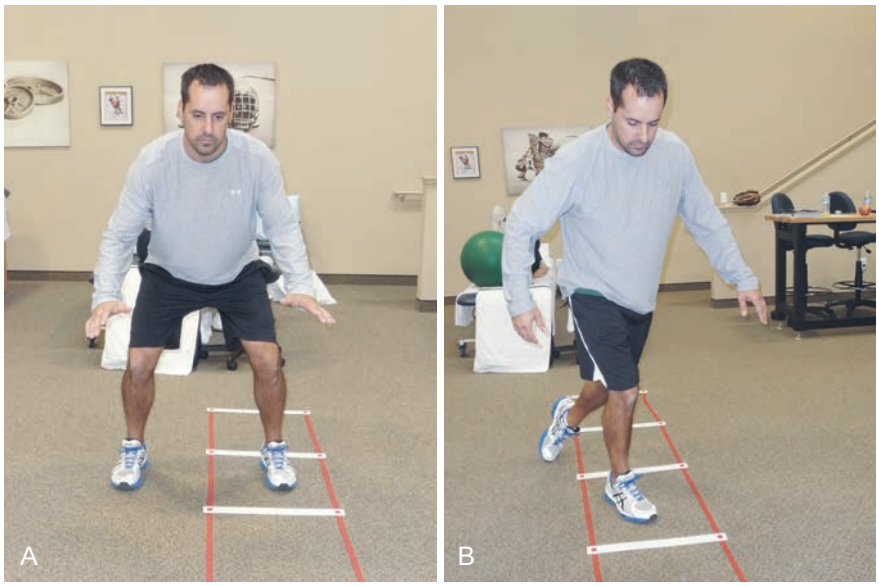

FIGURE 42-22. Photo demonstrating using agility ladder. Patient hops on both legs from one box to the next (**A**). Patient demonstrates a crossover step technique from in and out of the ladder (**B**).

Functional Exercises

- See therapeutic exercise section

Sport-Specific Exercises

- Light jogging, biking, plyometrics, agility ladder, shuffling, hopping, change of direction

Milestones for Progression to the Next Phase

- All exercises as in the preceding performed but particularly hopping exercises, higher-level agility ladder exercises, hop side to side, step-ups with hop, sets of 15 to 20 without pain.
- Jogging without gait compensation or residual pain. Cutting/twisting, higher load resistive training accomplished.
- Some soft tissue soreness can be noted, but is not limiting.

Phase IV (postoperative weeks 10 to 14)

Clinical Pearls

The patient or therapist works on dramatically increasing repetition and load. Constant testing and retesting are performed to make sure patient is progressing. Return to practicing specific sport and ready for return during this phase. Do everything as in the preceding but harder, faster, stronger and longer. It should take the patient 4 to 6 weeks at this time to return to his or her activity of choice. The patient will increase the intensity of exercise roughly 25% per week.

Goals

- Achieve significant strength gains in affected leg including:
  - Ability to perform a single leg calf raise through at least 80% of ROM during weight bearing
  - Single leg squat performed at 85% of total reps of uninvolved leg
  - Open chain manual muscle testing that is 5/5 for quads, hamstring, and gastroc/soleus complex
- Begin to see calf muscle girth increase.
- All exercises should be pain free.
- Progress to DC to HEP.

Management of Pain and Swelling

- NSAIDs only for pain
- Swelling should not be present.

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- Manual self-stretches for normal pelvic and extremity movement

Stretching and Flexibility Techniques for the Musculotendinous Unit

- Self-stretching ankle and plantar fascia techniques to maintain normal flexibility

Other Therapeutic Exercises

- Aggressive total body strengthening, as noted in preceding section

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- See previous section

Sensorimotor Exercises

- See previous section

Open and Closed Kinetic Chain Exercises

- Both types of exercises as tolerated and as noted in previous section

Techniques to Increase Muscle Strength, Power, and Endurance

- Same as previous section but progress total time of repetitions as tolerated.

Neuromuscular Dynamic Stability Exercises

- Same as previous section

Plyometrics

- Same as previous section

Functional Exercises

- Fast feet, lateral fast feet, scissor exercises, karaoke, lateral hopping, side-to-side hops, jump squats, step squats with weighted ball or kettle bells, lunges in all directions, box jumps (Figure 42-24)

Sport-Specific Exercises

- Progress as tolerated

Milestones for Progression to the Next Phase

- Athlete or patient should be ready to engage in sporting activity

Phase V (postoperative weeks 14 to 24)

Goals

- Athlete has returned to sport of choice
- Able to work through pain, if any
- Should have no limitation in function

FIGURE 42-24. Photo demonstrating Fast feet exercises.

Sensorimotor Exercises

- At this point, the athlete has returned to his or her specific sport of choice. Progressions at this point are focused on sport-specific movement patterns and performance enhancement.

Open and Closed Kinetic Chain Exercises

- Same as in the preceding

Techniques to Increase Muscle Strength, Power, and Endurance

- Same as in the preceding

Neuromuscular Dynamic Stability Exercises

- Same as in the preceding

Plyometrics

- Same as in the preceding

Functional Exercises

- Same as in the preceding

Sport-Specific Exercises

- Same as in the preceding

Milestones for Progression to the Next Phase

- Same as in the preceding

Criteria for Return to Sport

General

- Pain is present only during start-up activities and resolves quickly
- Equivalent ankle dorsiflexion and subtalar joint motion compared with contralateral side.
- Calf circumference is 85% of contralateral side and muscle definition present
- Able to perform 85% to 90% of repetitions of contralateral leg during single leg squat, calf raises, single leg balance, and proprioceptive exercises

Sport-Specific

- Able to perform 10 repetitions of a single heel rise
- Able to perform cutting, twisting and karaoke maneuvers
- Able to sprint 10 yards without pain
- For runners, ability to run normal course or circuit

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Daily calf/plantar fascial stretches

Exercises and Other Techniques for Prevention of Recurrent Injury

- Consider usage of accommodative orthotics for impact activities, such as running
- Patient education regarding his or her specific foot type and appropriate shoe wear, such as patients with pes planus, require "motion-control" footwear, and patients with a pes cavus foot type require more "accommodative" footwear.

Evidence

American Orthopaedic Foot & Ankle Society: AOFAS Position Statement: Endoscopic and Open Heel Surgery. http://www.aofas.org/i4a/pages/index.cfm?pageid=3680. Accessed April 29, 2008.

Position statement of the AOFAS discussing the treatment options including surgical intervention. (Level V evidence)

DiGiovanni DF: Tissue-specific plantar fascia-stretching exercise enhances outcomes in patients with chronic heel pain. A prospective, randomized study. *J Bone Joint Surg Am* 85-A:1270–1277, 2003.

This prospective, randomized, non-blinded study compared calf stretches to a plantar fascia specific stretch and assessed outcome. Plantar fascia specific stretches were noted to eliminate or significantly improve symptoms versus calf stretches at 8 week follow-up. (Level I evidence)

Gudeman SD: Treatment of plantar fasciitis by iontophoresis of 0.4% dexamethasone. A randomized, double-blind, placebo-controlled study. *Am J Sports Med* 25:312–316, 1997.

This study noted very short-term improvement in the patient group treated with iontophoresis versus the group treated without this modality. Both groups were also treated with ice, stretches, and orthoses. (Level I evidence)

Osborne HR: Treatment of plantar fasciitis by LowDye taping and iontophoresis: Short term results of a double blinded, randomized, placebo controlled clinical trial of dexamethasone and acetic acid. *Br J Sports Med* 40:545–549, 2006.

The iontophoresis group had less pain in short-term follow-up versus two control groups. (Level I evidence)

Porter D: The effects of duration and frequency of Achilles tendon stretching on dorsiflexion and outcome in painful heel syndrome: A randomized, blinded, control study. *Foot Ankle Int* 23:619–624, 2000.

Three groups were compared with different frequency/duration of stretching exercises versus a no-stretch control group. The two groups that were directed to perform stretches were noted to have a decreased level of pain at follow-up compared to controls. (Level I evidence)

Radford JA: Effectiveness of low-Dye taping for the short-term treatment of plantar heel pain: A randomized trial. *BMC Musculoskelet Disord* 7:64. http://dx.doi.org/10.1186/1471-2474-7-64, 2006.

Short-term (1 week) improvement in start-up pain was noted in the group treated with taping plus ultrasound versus the group with just ultrasound treatment in a group of 92 patients. (Level I evidence)

Multiple Choice Questions

QUESTION 1. Which one of the following is one of the indications for surgical intervention in the patient with plantar fasciitis?

A. Ongoing plantar heel pain despite 9 months of conservative treatment
B. Inability of a runner to complete his or her training for a marathon
C. Patient with heel pain does not want to go through 6 weeks of physical therapy
D. Patient with 2 weeks of heel pain that is in between two sports and has a 6-week time frame to "get well"

QUESTION 2. When is a gastrocnemius release considered as an adjunctive procedure in a patient who is considered for surgical partial plantar fascia release?

A. This procedure is considered in all patients who will undergo a partial plantar fascial release.
B. A positive Silverskold test
C. In the patient who complains of "tightness" in the Achilles after a run
D. In the patient with a demonstrable hamstring contracture

QUESTION 3. During what time frame (in weeks) of rehabilitation after surgery for a partial plantar fascial release is the initiation of strengthening appropriate?

A. Week 1
B. Week 2 to 6
C. Week 6 to 12
D. Week 12 to 16

QUESTION 4. When should the athlete be ready to engage in his or her normal sporting activity?

A. Week 2 to 6
B. Week 6 to 10
C. Week 10 to 14
D. Week 14 to 24

QUESTION 5. What is the amount of ankle dorsiflexion is needed for normal gait?

A. 10°
B. 20°
C. 30°
D. dorsiflexion to a neutral position

Answer Key

QUESTION 1. Correct answer: **A** (see Indications for Surgical Treatment)

QUESTION 2. Correct answer: **B** (see Indications for Surgical Treatment)

QUESTION 3. Correct answer: **B** (see Phase II)

QUESTION 4. Correct answer: **C** (see Phase IV)

QUESTION 5. Correct answer: **A** (see Phase II)

Chapter 43

Midfoot Strains and Sprains and Lisfranc Injuries

INTRODUCTION

Jason M. Jennings, MD, DPT, and Mark E. Easley, MD

Epidemiology of Tarsometatarsal Complex Injuries (Lisfranc Complex Injuries)

- Tarsometatarsal (TMT) complex injuries are rare and often subtle in athletes both clinically and radiographically.[1] They typically occur secondary to a low-energy indirect force in contrast to the majority of nonathletic injuries, which result from high-energy direct forces (i.e., motor vehicle accident).
- Midfoot sprains in athletes represent a spectrum of injuries to the Lisfranc ligament complex from partial sprains with no diastasis (stage I) to complete tears with frank diastasis (stages II and III) (Figure 43-1).[2]

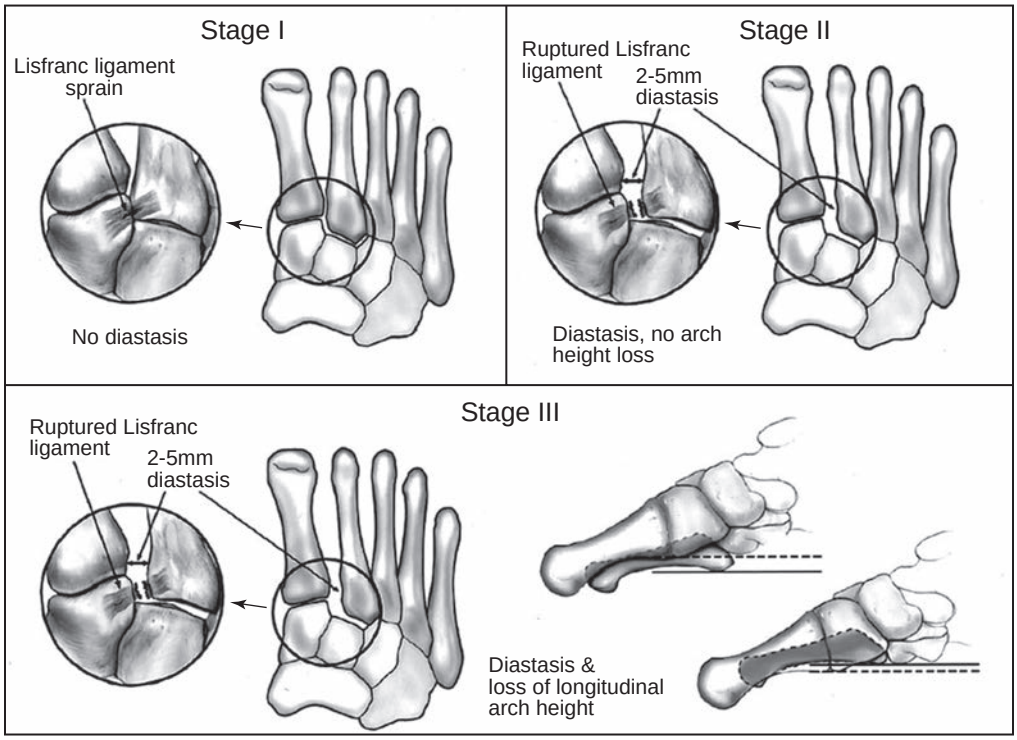

FIGURE 43-1. Nunley and Vertulla classification of ligamentous Lisfranc injuries *(Adapted from Nunley JA, Vertullo CJ: Classification, investigation, and management of midfoot sprains. Lisfranc injuries in the athlete.* Am J Sports Med *30(6):871-878, 2002, with permission.)*

- Twenty percent misdiagnosed at initial presentation, with 40% receiving no treatment in the first week.[3]

Incidence

- Increased incidence in athletes secondary to greater appreciation and recognition
- Four percent of college football players per year[4]
  - 29.2% of these players were offensive linemen

Age

- Most common in third decade

Sex

- Males affected two to four times more often than females[3]

Sport

- Most common sports: football, equestrian, windsurfing, gymnastics, basketball, baseball, other
- Women's gymnastics is one of the highest injury-producing sports, with many of these injuries requiring surgical intervention.[3]

Position

- Offensive lineman[4]

Pathophysiology

Intrinsic Factors

- The midfoot is typically divided into three columns:
  - Medial column: navicular, medial cuneiform, and the first metatarsal
  - Middle column (most rigid): articulation between the second and third metatarsals with their respective articulation
  - Lateral column (most mobile): articulation between the fourth and fifth metatarsals and the cuboid
- The Lisfranc ligament is located between the medial cuneiform and the base of the second metatarsal providing stability between the medial and middle columns.
- There is no ligamentous attachment between the first and second metatarsal joint.[5]
- The plantar ligaments are stronger than the dorsal ligaments which may account for dorsal dislocations when they occur.[6]
- The base of the second metatarsal is recessed between the medial and lateral cuneiforms creating the "keystone" in the shape of a Roman arch, which provides inherent osseous stability.
- In patients with injuries to the Lisfranc joint, the medial mortise depth (medial aspect of the TMT joint, between the medial cuneiform and the base of the second metatarsal) has been shown to be shallower, decreasing osseous stability and thus increasing risk to injury.[7]

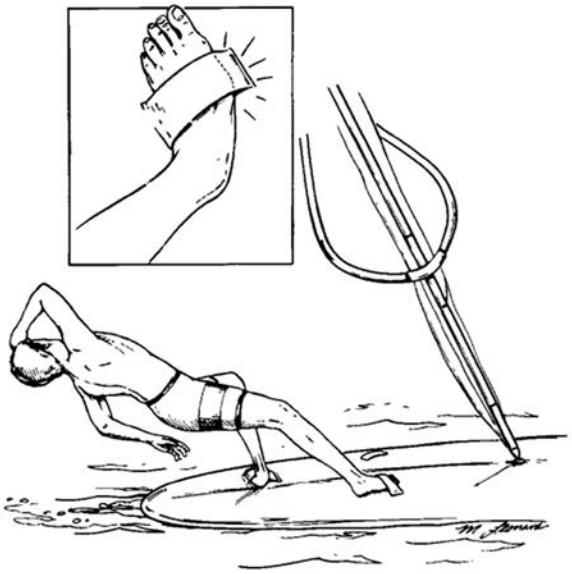

FIGURE 43-2. Mechanism of a windsurfing injury—a fall backward causing forced equines of the fixed forefoot. *(Adapted from Curtis MJ, Myerson M, Szura B: Tarsometatarsal joint injuries in the athlete.* Am J Sports Med *21:497-502, 1993, with permission.)*

Extrinsic Factors

- Interface between the athletic shoe and playing field, particularly artificial turf [8]
- Regular turf injuries in American football may be influenced by type of shoe or cleat worn and the forces on the foot when another athlete falls on it in a compromised position.[8]
- Stirrup creating a fulcrum effect on the forefoot as seen in windsurfing and equestrian sports (Figure 43-2)[9]

Traumatic Factors

- Athletic injuries of the TMT complex can be divided into three broad categories:
  - Plantar flexion injury: axial force applied along the longitudinal axis (Figure 43-3)
  - Forefoot forcefully abducted with hindfoot fixed[9] (i.e., windsurfing and equestrian sports) (see Figure 43-2)
  - Crush to the dorsum of the foot
- These mechanisms are oversimplifications, because there are probably varying patterns of each force (e.g., rotational).[8]

Clinical Presentation and Examination

- The presentation is often subtle, and one should have a high index of suspicion when the athlete presents with a midfoot "sprain."
- "Pop" felt over the dorsal aspect of the foot
- Inability to weight-bear

Abnormal Findings

- Physical examination findings are often subtle.
- Inability to weight-bear

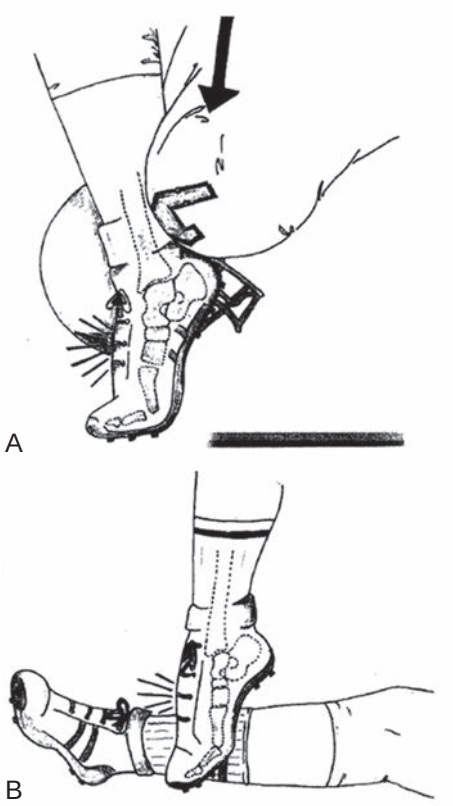

FIGURE 43-3. A, Plantarflexion of the foot driven into the ground by an opposing player falling on the hindfoot or leg. **B,** Another mechanism demonstrates a player's plantarflexed foot coming down on another player's leg during a pileup. *(Adapted from Meyer SA, Callaghan JJ, Albright JP, Crowley ET, Powell JW: Midfoot sprains in collegiate football players.* Am J Sports Med *22:392-401, 1994, with permission.)*

- Variable amount of edema
- Variable deformity
- Plantar arch ecchymosis
- Diastasis between the first and second toes
- Tender to palpation over the TMT complex
- Pain with pronation and abduction of the forefoot[9]
- Pain with passive plantar flexion, dorsiflexion, abduction, and adduction of the first and second metatarsal complex
- Coronal plane stress across the forefoot

Imaging

- Despite being associated with relatively minor radiographic changes, subtle TMT complex injuries can be a source of considerable morbidity in athletes.[3]
- Twenty to fifty percent of tarsometatarsal injuries are missed on initial non–weight-bearing radiographs.[2,6]
- False negative findings are associated with inability to weight-bear secondary to pain. If weight bearing is limited by pain, ankle block anesthesia may be used.[2]
- Standard weight-bearing radiographs
  - Anteroposterior: The medial border of the second metatarsal should be in alignment with the medial border of the middle cuneiform. With significant Lisfranc joint disruption this alignment will be compromised.

FIGURE 43-4. Radiograph of the foot demonstrating the fleck sign.

  - 30° internal oblique: The medial border of the fourth metatarsal should be aligned with the medial border of the cuboid. Disruption is indicative of a lateral column injury.
  - Lateral view: Note the continuity of the dorsal cortex of the first and second metatarsal to the medial and middle cuneiform. Flattening of the longitudinal arch, which is correlated with a worse functional outcome, is noted by measuring the distance from the plantar aspect of the fifth metatarsal and the plantar aspect of the medial cuneiform.[1]
  - Fleck sign: a small avulsion fragment noted over the lateral edge of the medial cuneiform or the medial aspect of the second metatarsal, which is indicative of a Lisfranc injury (Figure 43-4)
  - Associated injuries: base of second metatarsal, navicular, cuneiform, cuboid, or other
- Stress radiographs (pronation and abduction)[1] may be used to assist with diagnosis if weight-bearing and non–weight-bearing radiographs are normal or equivocal. Adequate anesthesia must be utilized secondary to pain when performing this maneuver. Many physicians will opt for MRI prior to performing stress radiographs.
- MRI: sensitive study for the diagnosis of subtle (stage I) midfoot ligamentous injuries when compared with intraoperative findings[10]
- Bone scintigraphy: diagnosis of subtle (stage I) midfoot injuries or those with delayed diagnosis[2]
- CT: Sensitive for fracture but remains limited in the athletic low-energy TMT complex injury for assessment of instability, and without weight-bearing stress or clear diastasis, the status of the joint stability remains unclear.[6]

Differential Diagnosis

- Midfoot sprain is a tarsometatarsal complex injury until proved otherwise.

Treatment

Nonoperative Management

- Non–weight-bearing immobilization
- Weight-bearing immobilization

Guidelines for Choosing Among the Nonsurgical Treatment Options

- Stage I (no diastasis) Lisfranc ligament sprain
- It is the authors' preference to allow the patient to weight bear as tolerated in a cam walker for the first 6 weeks. Serial weight-bearing radiographs are obtained at 2 and 6 weeks to assure there is no diastasis or instability.

Surgical Indications

- Absolute: Stage II and III Lisfranc ligament sprains, displaced fractures, subluxation/dislocation
- Relative: continued pain and failed conservative treatment for stage I injuries
- Table 43-1 lists five steps that can be used to determine the need for surgical intervention based on imaging studies

Aspects of History, Demographics, or Exam Findings That Affect Choice of Treatment

- Low-energy (athletes) versus high-energy injury
- Associated injuries
- Operative treatment is generally indicated for all obvious displaced injuries (stage II and III injuries).
- The patient with minimal ambulatory ability, an insensate foot, or preexisting inflammatory arthritis *may* be best treated nonoperatively.

Aspects of Clinical Decision Making When Surgery Is Indicated

- Open versus closed injury
- Vascular status
- Compartment syndrome
- Timing of surgery
- Delay in diagnosis
- ORIF versus arthrodesis versus percutaneous screw fixation
- Postoperative management and the patient's ability to comply with the strict non–weight-bearing status and rehabilitation protocol

Evidence

Curtis MJ, Myerson M, Szura B: Tarsometatarsal joint injuries in the athlete. *Am J Sports Med* 21:497–502, 1993.

This study was a retrospective review of 19 patients who injured the tarsometatarsal joint complex during athletic competition. Stress fluoroscopy of the articulation under anesthesia was used to supplement clinical and radiographic examination. Poor functional results were seen in those where diagnosis was delayed and inadequately treated unstable injuries with nonoperative immobilization. (Level III evidence)

DeOrio M, Erickson M, Usuelli FG, et al: Lisfranc injuries in sport. *Foot Ankle Clin N Am* 14:169–186, 2009.

This article reviews anatomy, classification, diagnosis, and treatment of Lisfranc injuries in sport. In addition, the authors' preferred operative technique is discussed in detail. (Level V evidence)

Faciszewski T, Burks RT, Manaster BJ: Subtle injuries of the Lisfranc joint. *J Bone Joint Surg* 72A:1519–1522, 1990.

Fifteen patients with 18 subtle Lisfranc joint disruption demonstrated weight-bearing. Lateral radiographs are needed to identify flattening of the longitudinal arch. Maintenance of the longitudinal arch was associated with better functional outcomes. (Level III evidence)

Meyer SA, Callaghan JJ, Albright JP, et al: Midfoot sprains in collegiate football players. *Am J Sports Med* 22:392–401, 1994.

This retrospective study of 23 collegiate football players demonstrated an incidence of 4% of football players per year, with 29.2% of these players offensive lineman. The patients

Table 43-1 Stepwise Evaluation of a Patient with Lisfranc Injury to Determine Whether to Perform Nonsurgical or Surgical Treatment

Step	Study	Result	Recommendation	Rationale
1	Physical examination	Plantar bruising, painful piano key test, midfoot swelling	Obtain weight-bearing radiographs unless injury is obvious with non–weight-bearing images	Weight-bearing radiographs are always useful, but oblique views may be helpful for the tentative patient.
2	Radiography	Loss of arch on comparative weight-bearing lateral radiograph, widening between the first and second metatarsal vases or comparative AP views, fleck sign	ORIF is indicated with positive results. External rotation views are necessary when there is uncertainty based on plain radiographs or the patient cannot bear weight. When uncertainty remains, MRI is useful.	Any measurable subluxation is an indication for ORIF. When in doubt, proceed with further tests. On MIR, edema indicates midfoot injury, and subluxation confirms Lisfranc injury.
3	MRI	Edema at the tarsometatarsal joint, bone bruise, subluxation, or ligament tear	If edema but no ligament tear or subluxation, then CT is recommended. Perform ORIF in the presence of subluxation or a clear ligament tear.	MRI is more sensitive to edema in subtle injuries. CT may better illustrate subluxation, but MRI may show both.
4	CT	1 mm of subluxation	Strong evidence for Lisfranc injury when edema is noted on MRI and subluxation on CT. ORIF is indicated.	MRI with edema and no ligament tear combined with normal CT requires stress examination under anesthesia, with possible ORIF.
5	Stress examination	Subluxation	ORIF	When negative, treat as a sprain

From Watson TS, Shurnas PS, Denker J: Treatment of Lisfranc joint injury: Current concepts. JAAOS 18(12):718–728, 2010.

were followed for a mean of 30.8 months and most of despite a prolonged restriction from activity most of the players reported minor residual problems. (Level III evidence)

Myerson MS, Cerrato RA: Current management of tarsometatarsal injuries in the athlete. *J Bone Joint Surg* 90-A:2521–2533, 2008.

This instructional course lecture presents the anatomy, clinical presentation, diagnostic imaging, nonoperative and operative management of tarsometatarsal injuries in the athlete. (Level V evidence)

Nunley JA, Vertullo CJ: Classification, investigation, and management of midfoot sprains. Lisfranc injuries in the athlete. *Am J Sports Med* 30(6):871–878, 2002.

This retrospective cohort study utilized weight bearing radiographs and bone scintigrams to diagnose Lisfranc injuries in 15 athletes who were treated operatively versus nonoperatively according to the following classification system: nonoperative management for stage I injuries (nondisplaced) and anatomic reduction with fixation of stage II (diastasis with no arch height loss) and stage III (diastasis with arch height loss) injuries (Figure 1). Excellent outcomes were reported in 93% of their patients. They concluded that weight-bearing radiographs and bone scintigrams are sensitive, reproducible, and relatively inexpensive methods to investigate this injury. Anatomic alignment was the key to excellent functional outcomes.(Level IV evidence)

Peicha G, Labovitz J, Seibert FJ, et al: The anatomy of the joint as a risk factor for Lisfranc dislocation and fracture-dislocation. An anatomical and radiological case control study. *J Bone Joint Surg Br* 84(7):981–985, 2002.

This case control study of 33 patients with Lisfranc injuries evaluated the relationship between the medial and lateral cuneiforms to determine if there were anatomical features that may predispose these patients to injury. The depth of the medial mortise (medial aspect of the tarsometatarsal joint, between the medial cuneiform and the base of the second metatarsal) in patients with injuries to the Lisfranc joint was found to be shallower than the control group. (Level III evidence)

Raikin SM, Elias I, Dheer S, et al: Prediction of midfoot instability in subtle Lisfranc injury. Comparison of magnetic resonance imaging with intraoperative findings. *J Bone Joint Surg Am* 91: 892–899, 2009.

This retrospective review of 21 tarsometatarsal complex injuries correlated conventional MRI with manual stress radiographic evaluation and surgical findings. The strongest predictor of instability, and thus an unstable midfoot, was disruption (rupture or grade 2 sprain) of the plantar ligament between the medial cuneiform and the bases of the second and third metatarsals, with sensitivity, specificity, and positive predictive value of 94%, 75%, and 94%, respectively. The appearance of a normal ligament is suggestive of a stable midfoot. An MRI may alleviate the need for stress radiographic evaluation under anesthesia. (Level II evidence)

Shapiro MS, Wascher DC, Finerman GA: Rupture of Lisfranc's ligament in athletes. *Am J Sports Med* 22: 687–691, 1994.

Nine athletes with Lisfranc ligament disruptions were presented in this retrospective review article. Nonoperative management was successful in returning the athletes back to competition in an average of 4 months. (Level III evidence)

Watson TS, Shurnas PS, Denker J: Treatment of Lisfranc joint injury: Current concepts. *J Am Acad Orthop Surg* 18:718–728, 2010.

This review article outlines current concepts regarding classification, diagnosis, and treatment of injuries to the Lisfranc complex. (Level V evidence)

Multiple Choice Questions

QUESTION 1. Which statement is false regarding the tarsometatarsal complex?

A. The Lisfranc ligament is located between the medial cuneiform and the base of the second metatarsal.
B. The plantar ligaments are stronger than the dorsal ligaments.
C. The ligamentous attachment between the first and second metatarsal provides most of the structural support.
D. The base of the second metatarsal is recessed between the medial and lateral cuneiforms.

QUESTION 2. Which imaging modality has limited use in the diagnosis of pure ligamentous tarsometatarsal complex injuries?

A. Weight-bearing radiographs
B. Stress radiographs
C. MRI
D. Bone scintigraphy
E. CT scan

Answer Key

QUESTION 1. Correct answer: **C** (see Intrinsic Factors that Predispose to Injury)

QUESTION 2. Correct answer: **E** (see Imaging Studies)

NONOPERATIVE REHABILITATION OF MIDFOOT SPRAINS (STAGE I LIGAMENTOUS LISFRANC INJURIES)

Eric R. Schweitzer, DPT, OCS, MTC, Lacy D. Jennings, DPT, SCS, MTC,
Mark E. Easley, MD, and Jason M. Jennings, MD, DPT

GUIDING PRINCIPLES OF REHABILITATION

- Understand:
  - Stage I ligamentous Lisfranc injuries in athletes (see Introduction)
  - Importance of serial radiographs throughout rehabilitation progression
  - Specific intrinsic rehabilitation strengthening exercises for the Lisfranc injury
- Proper selection of exercise and sport-specific progressions
- Provide thorough rehabilitation and treatment so to restore normal foot and lower extremity function
- Patient education regarding injury prevention and footwear modification

Phase I (weeks 0 to 6)

Protection

- Controlled ankle motion (CAM) boot immobilization at all times except for physical therapy–specific exercises
- Weight-bearing as tolerated with crutches. Pain to dictate how much weight.
- Heel lift in the opposite shoe to avoid pelvic asymmetries
- Weight-bearing radiographs at the 2- and 6-week marks. Any diastasis indicates failed nonoperative management.

Management of Pain and Swelling

- Elevate lower leg above heart level
- Nonsteroidal anti-inflammatory drugs (NSAIDs)
- Ice

TIMELINE 43-1: **Nonoperative Rehabilitation of Midfoot Sprains**

PHASE I (weeks 0 to 6)

- Cast (or CAM boot) immobilization, WBAT with crutches
- Cardiovascular conditioning: UBE, pool, bike
- Aquatic therapy: initiated at week 2 starting in shoulder deep water
- Elevated ankle pumps, circles, ABCs
- Using basic LE program with gait training WBAT
- PRICE for inflammation
- LE stretching neighboring joints and proximal joint strengthening core, hip, and knee
- Contralateral limb proprioceptive training
- X-ray at 2 and 6 weeks to determine removal of boot and WB progressions

PHASE II (weeks 6 to 10)

- PWB → WBAT over 1 week with the use of custom orthotic and
- Stiff sole shoe
- Aquatic therapy progressions:
  - Shoulder → waist deep water
  - Double leg → single leg exercises
  - Hop → jump
  - Fast walk → jog → run
- Proprioception progressions:
  - Partial weight bearing → full weight bearing
- Double leg exercise → single leg exercise
- Eyes open → eyes closed
- Level surface → uneven surface
- Perturbations:
  - Submaximal → maximal
  - Slow → fast
  - Known (proactive) → unknown (reactive) patterns
  - Strengthening:
  - Intrinsic foot musculature
  - Gastrocnemius/soleus, tibialis anterior, tibialis posterior and peroneal longus/brevis
  - Strengthening progressions
- Submaximal → maximal intensity
- Short arc → full arc
- Isometric → concentric → eccentric
- Gait training on land (aquatic → land)
- Plyometrics progressions:
  - Aquatic → land
  - In place → forward, backward and lateral over tape
  - Bilateral → Single leg
  - Flat ground → small box (2 inch) gradually increasing the size as needed for particular sport
  - One plane of movement (frontal) → multiple planes of movement (frontal and transverse)
- May begin land and jogging on the treadmill at week 8 if the athlete is able to tolerate
- Weight-bearing radiographs at 10 weeks. Evidence of diastasis is failure of nonoperative intervention.

- Ace wrap/compression
- Ankle pumps, circles, ABCs

Therapeutic Exercises

- Core exercises, upper extremity and contralateral lower extremity strengthening
  - Upper body ergometer is utilized for cardiovascular fitness
- Aquatic therapy: initiated at week 2. Basic progressions as follows:
  - Shoulder → waist deep water
  - Double leg → single leg exercises

Sensorimotor Exercises

- Contralateral limb proprioceptive training including single leg balance
- Early pain-free protected weight-bearing (CAM walker), for proprioceptive input

Milestones/Criterion-Based Rehabilitation Guidelines to Progress to the Next Stage

- Stable radiographic alignment with no evidence of diastasis at 2 and 6 weeks.
- Minimal tenderness with palpation over the Lisfranc complex—progress to Phase II.
- Diastasis indicates failure of nonoperative management.

Phase II (weeks 6 to 10)

Protection

- At 6 weeks, a custom-molded orthosis is prescribed and the athlete is allowed to ambulate in a stiff-soled shoe.
- As weight-bearing is introduced, initially reduce forefoot loading during push off.[1]
- Midfoot taping may assist in plantarflexion of the first ray, which helps to stabilize forefoot and support longitudinal arch in beginning stages of functional training (Figure 43-5).

Management of Pain and Swelling

- Gradual increase in pain-free weight-bearing therapeutic exercise will help to further reduce pain and edema. Continue with elevation as in Phase I. Begin with selective modalities as needed (i.e., ice and electrical stimulation).

TIMELINE 43-1 **Nonoperative Rehabilitation of Midfoot Sprains** (Continued)

PHASE III (weeks 10 to 12)	PHASE IV (weeks 12+)

• Continue progressions per phase II
• Sport-specific training progressions
  • Aquatic → land
  • In-line activity → cutting
  • Wide arching → tighter sharp turns
  • Slow → fast
  • Flat surface → uneven surface
  • Know → unknown game situations
• Progression of plyometrics (sport-specific)
• Rarely the patient is able to return to sport during this phase
	• Assessment of footwear (i.e., cleats and stirrup)
	• Assessment of field as related to footwear (i.e., natural grass vs. artificial turf)
	• A stiff insoled shoe with a custom orthotic should be worn when the athlete returns to sport
	• Continue sport-specific training as needed
	• Return to sport
	• If the athlete is still experiencing pain or unable to progress according to the rehabilitation protocol refer back to MD (orthopaedic foot and ankle specialist)

FIGURE 43-5. Lisfranc taping technique. Tape begins and ends on dorsomedial aspect of the first metatarsal and loops around the heel as pictured. The tape aims to improve plantarflexion of the first ray, as can be seen in the positional relationship versus the second ray in the picture. A horizontal anchor across the midfoot is also shown. *(From Wadsworth DJ, Eadie NT: Conservative management of subtle Lisfranc injury: A case report.* J Orthop Sports Phys Ther *35:154–164, 2005, with permission.)*

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- No joint mobilizations because of emphasis on stabilization of the midfoot

Stretching/Flexibility Techniques for the Musculotendinous Unit

- Gastrocnemius/soleus complex stretching with care not to fulcrum across the midfoot region (i.e., standing wall stretch recommended over long sit towel stretching) (Figure 43-6).
- Continue stretching proximal musculature as needed.

FIGURE 43-6. Ankle dorsiflexion measurement and treatment in weight bearing. Measure how far the athlete can slide foot away, keeping the heel planted, and touch the knee to the wall. Hold the subtalar joint in neutral throughout the test. Measure from tip of the hallux to the wall. *(From Hudson Z: Rehabilitation and return to play after foot and ankle injuries in athletes.* Sports Med Arthrosc Rev *17:203–207, 2009.)*

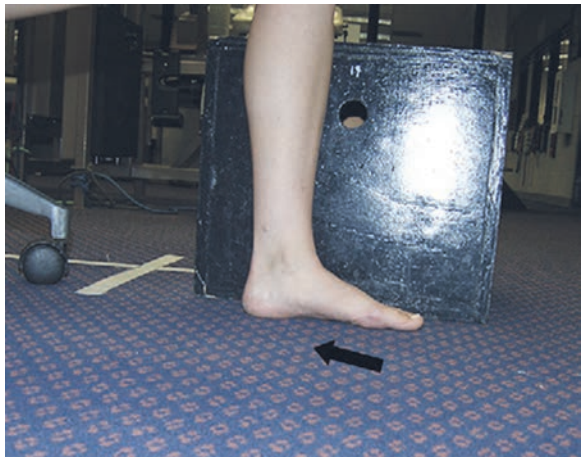

FIGURE 43-7. Short foot exercise contracts the plantar intrinsic muscles. Ask the patient to "cup" the arch upward as a palm of a hand might cup water. Emphasis should be placed on minimizing extrinsic muscle activity. *(From Chin L, Hertel J: Rehabilitation of ankle and foot injuries in athletes.* Clin Sports Med *29:157–167, 2010, with permission.)*

Other Therapeutic Exercises

- Continue core, hip, and knee therapeutic exercise. Treatment adjusted based on residual deficits found in ongoing reevaluations.
- Progression of aquatic therapy regimen—basic progressions as the athlete tolerates:
  - Shoulder → waist-deep water
  - Double leg → single-leg exercises
  - Hop → jump
  - Fast walk → jog → run

Activation of Primary Muscles Involved

- Intrinsic foot muscle strengthening (Figures 43-7 and 43-8):
  - Towel scrunches and marble grabs

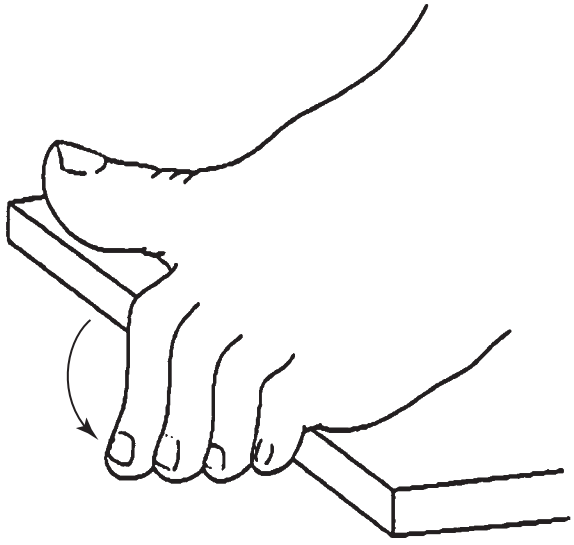

FIGURE 43-8 Intrinsic toe flexors isolation by contracting the extensor hallicus longus to inhibit the ability of the long toe flexors to contract. *(Redrawn from Mulligan E: Leg, ankle and foot rehabilitation. In: Andrews JR, Harrelson GH, Wilk KE, editors.* Physical rehabilitation of the injured athlete, *3rded. Philadelphia, 2004, Saunders, pp. 329-376, withpermission.)*

- Gastrocnemius and soleus:
  - Concentric progressed to eccentric
  - Retrain at heel strike to decelerate tibial internal rotation and control the lower limb moving over the foot.
  - Controlled pronation by gastrocnemius and soleus allows forces to disperse to avoid excessive loading on individual tissues.
- Posterior tibialis:
  - Supination and inversion allow the foot to become a rigid lever for push off, which stabilizes the midtarsal joint in the stance phase.
  - The broad insertion of the posterior tibialis tendon plantar supports the transverse arch.[2]
- Peroneus longus:
  - Supports the transverse arch in the late stage midstance and early heel off
  - Primary function is plantarflexion of the first ray
  - It is the primary stabilizer of the first ray (Figure 43-9).[1]
  - Assists with the transfer of body weight from the lateral to the medial side of the foot by everting the foot[2]

Sensorimotor Exercises

- Proprioception progressions: Particular exercises are selected based on the athletes' stage and progression. Begin gentle and progress with objectively demonstrated tolerance:
  - Partial weight bearing → full weight bearing
  - Double leg exercise → single leg exercise
  - Eyes open → eyes closed
  - Level surface → uneven surface
  - Shoes on → shoes off
  - Perturbations:
    - Submaximal → maximal
    - Slow → fast
    - Known (proactive) → unknown (reactive) patterns

FIGURE 43-9. Isometric contraction of the first metatarsal head into the ground while maintaining longitudinal arch for peroneus longus strengthening. *(From Wadsworth DJ, Eadie NT: Conservative management of subtle Lisfranc injury: A case report.* J Orthop Sports Phys Ther *35:154–164, 2005.)*

Open and Closed Kinetic Chain Exercises

- Principles of therapeutic exercise parameter progressions are based on the athlete's progress. Refer to the muscle activation section for specific exercises.
  - Submaximal → maximal intensity
  - Short arc → full arc
  - Isometric → concentric → eccentric
- OKC exercises:
  - Plantarflexion (gastrocnemius/soleus)
  - Dorsiflexion (tibialis anterior)
  - Inversion (tibialis posterior)
  - Eversion (peroneal longus/brevis)
- CKC exercises:
  - Heel raises (gastroc/soleus)
  - Exercises using an unstable surface
  - Kinetic chain exercises

Techniques to Increase Muscle Strength, Power, and Endurance

Neuromuscular Dynamic Stability Exercises

- Single leg stance on foam/disc with opposite limb moving against band resistance × 4 cardinal planes
- Lunging into disc/foam
- Lunge off elevated surface for increased loading

Plyometrics

- Initial plyometric type exercises are started in aquatic therapy (i.e., hop, jump)
- Jumping
- In place → forward, backward, and lateral over tape
- Flat ground → small box (2-inch) gradually increasing the size as needed for particular sport
- Bilateral → single leg
- One plane of movement (frontal) → multiple planes of movement (frontal and transverse)

Functional Exercises

- Gait training with use of aquatic therapy and treadmill training.
- Combine movements and various challenges to improve functional strength and proprioception (Figure 43-10)

Sport-Specific Exercises

- May begin sport-specific drills utilizing aquatic therapy
- The athlete may initiate running at 8 weeks when he or she has achieved full pain-free ROM, strength, balance, and normalization of gait mechanics. In our experience, the athlete typically is unable to begin these progressions on land until 10 weeks postinjury.
  - Jogging → running → sprints

Milestones/Criterion-Based Rehabilitation Guidelines to Progress to the Next Stage

- Pain-free activity
- Full ROM, balance and strength
  - Star excursion balance test criteria: pain free activity, no diastasis on follow-up weight-bearing radiographs, normalization of gait mechanics with normal forefoot loading during push-off.

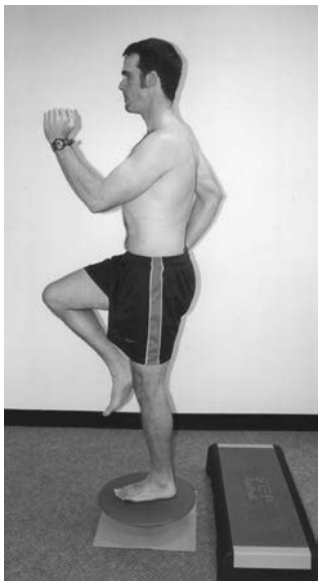

FIGURE 43-10. "Running Man." This exercise combines proprioception and gluteal strengthening with contraction of the peroneus longus and tibialis posterior. The stance foot can be on a multiplane board (start with flat surface) while the other foot is on a step. The athlete performs a running action using hip and knee flexion while swinging the arms and focusing on contracting the gluteals by maintaining neutral pelvis height and preventing internal rotation of stance leg. The swing phase leg should be going through hip and knee flexion without rotation or abduction. It is important that an athlete is able to isolate the gluteal activation independently before performing this exercise. *(From Wadsworth DJ, Eadie NT: Conservative management of subtle Lisfranc injury: A case report.* J Orthop Sports Phys Ther *35:154–164, 2005, with permission.)*

  - Strength testing: manual muscle testing, isometric, isotonic and isokinetic strength testing, single leg calf raises with knee extended and flexed.
  - Muscle groups: dorsiflexion, plantarflexion, eversion, inversion
- Normalization of gait mechanics
- Tolerates initial sport-specific exercises
- No evidence of diastasis on follow-up weight-bearing radiographs

Phase III (weeks 10 to 12)

Protection

Continued custom orthotic use for support of tarsometatarsal complex.

Techniques for Progressive Increase in Range of Motion

Stretching/Flexibility Techniques for the Musculotendinous Unit

- Continued stretching per Phase II. Serial assessments will guide specific changes.

Other Therapeutic Exercises

- Functional sport-specific strengthening
  - Core—planks, side planks, quadruped UE/LE lifts, therapeutic activity progressions, Pilates-based abdominal series and hip series: hundreds, roll up, single and double leg stretch, hip circles, hip abduction and flexion/extension, hip passes

Activation of Primary Muscles Involved

- Continue specific muscle strengthening per Phase II as needed

Sensorimotor Exercises

- Proprioception progressions per Phase II with emphasis on perturbation and sport-specific training
  - Perturbations
    - Submaximal → maximal
    - Slow → fast
    - Known (proactive) → unknown (reactive) patterns
  - Sport specific
    - Known → unknown game situations
- Open (OKC) and closed (CKC) kinetic chain exercises:
  - Sport-specific OKC and CKC strengthening (Figures 43-11 and 43-12)

Techniques to Increase Muscle Strength, Power, and Endurance

Neuromuscular Dynamic Stability Exercises

- Plyometrics:
  - Sport-specific hopping and jumping exercises. Progress per Phase II.
- Functional exercises:
  - Agility ladder drills
  - Box jumps—double leg to single leg—varying heights
- Sport-specific exercises:
  - Varies depending on the particular sport. Here are the general guidelines for progression in a pain-free manner:

FIGURE 43-11. Closed kinetic chain foot therapeutic exercise.

FIGURE 43-12. Open and closed kinetic chain therapeutic exercise for entire lower extremity.

- Aquatic → land
- In-line activity → cutting
  - Wide arching → tighter sharp turns
  - Slow → fast
- Flat surface → uneven surface
- Known → unknown game situations

Milestones/Criterion-Based Rehabilitation Guidelines to Progress to the Next Stage

- Pain-free sport-specific activity
- Occasionally the athlete is able to return to his or her respective sport before 12 weeks. We allow this on a case-by-case basis provided the athlete is able to demonstrate pain-free activity and has no limitations with functional and sports-specific drills.

Phase IV (greater than weeks 12): Return to Function/Sport

Protection

- Assessment of footwear (i.e., cleats and stirrup)
- Assessment of field as related to footwear (i.e., natural grass vs. artificial turf)
- A stiff-soled shoe should be worn to provide midfoot stability.
- Continued use of custom orthotics

Therapeutic Exercises

- Continue functional sport-specific strengthening as needed.
- Sport-specific balance and proprioception stimulation as needed
- Sport specific open and closed chain therapeutic exercise as needed
- Increase muscle strength, power, and endurance: Continue per Phase III.
- Neuromuscular dynamic stability exercises: Continue per Phase III.
- Sport-specific plyometric training as needed
- Functional exercises mimicking the sport-specific movements as needed
- Sport-specific exercises mimicking the sport-specific movements as needed

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- Demonstrates proficiency in initial sport-specific training drills
- Pain-free sport specific training drills

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or Other More Invasive Intervention

- Diastasis noted on serial weight-bearing radiographs
- Persistent pain and dysfunction with inability to progress through rehabilitation protocol

Transition to Performance Enhancement: Tips and Guidelines

- Once pain is eliminated and full sport tolerance is achieved, established performance enhancement concepts may be applied to the athlete's training.

Performance Enhancement and Beyond Rehab: Training/Trainer, and Optimization of Athletic Performance

- Performance enhancement will depend on the athlete's sport. Advanced, sport-specific plyometrics is an example of appropriate performance enhancement for running, cutting, and jumping sports. Typically Phases III and IV are performed by the athlete in conjunction with the team trainer, with serial assessments from the treating physician and physical therapist.

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Serial weight-bearing radiographs without evidence of diastasis or instability
- Pain-free sport-specific drills

Evidence

Chin L, Hertel J: Rehabilitation of ankle and foot injuries in athletes. *Clin Sports Med* 29:57–167, 2010.

This article details the general principles associated with rehabilitation of ankle and foot injuries in the athlete. Many of the therapeutic exercises and other treatments proposed for common foot/ankle injuries can be applied to midfoot sprains. (Level V evidence)

Curtis MJ, Myerson M, Szura B: Tarsometatarsal joint injuries in the athlete. *Am J Sports Med* 21:497–502, 1993.

This study was a retrospective review of 19 patients who injured the tarsometatarsal joint complex during athletic competition. Stress fluoroscopy of the articulation under anesthesia was used to supplement clinical and radiographic examination. Poor functional results were seen in those where diagnosis was delayed and inadequately treated unstable injuries with nonoperative immobilization. (Level III evidence)

DeOrio M, Erickson M, Usuelli FG, et al: Lisfranc injuries in sport. *Foot Ankle Clin North Am* 14:169–186, 2009.

This article reviews anatomy, classification, diagnosis, and treatment of Lisfranc injuries in sport. In addition, the authors' preferred operative technique is discussed in detail. (Level V evidence)

McKeon PO, Hertel J: Systematic review of postural control and lateral ankle instability, part II: Is balance training clinically effective? *J Athl Train* 43(3);305–315, 2008.

This study is a systematic review to see if prophylactic balance and coordination training can reduce risk of lateral ankle sprains, improve treatment outcomes associated with acute lateral ankle sprains, and improve outcomes in patients with chronic ankle instability. This study showed that balance training can be used prophylactically or after acute ankle strains to help reduce further ankle sprains, but unable to determine the effectiveness with outcomes of chronic ankle sprains. (Level V evidence)

Meyer SA, Callaghan JJ, Albright JP, et al: Midfoot sprains in collegiate football players. *Am J Sports Med* 22:392–401, 1994.

This retrospective study of 23 collegiate football players demonstrated an incidence of 4% of football players per year, with 29.2% of these players offensive lineman. The patients were followed for a mean of 30.8 months and most, despite a prolonged restriction from activity, reported minor residual problems. (Level III evidence)

Myerson MS, Cerrato RA: Current management of tarsometatarsal injuries in the athlete. *J Bone Joint Surg* 90-A:2521–2533, 2008.

This instructional course lecture presents the anatomy, clinical presentation, diagnostic imaging, and nonoperative and operative management of tarsometatarsal injuries in the athlete. (Level V evidence)

Nunley JA, Vertullo CJ: Classification, investigation, and management of midfoot sprains. Lisfranc injuries in the athlete. *Am J Sports Med* 30(6):871–878, 2002.

This retrospective cohort study used weight-bearing radiographs and bone scintigrams to diagnose Lisfranc injuries in 15 athletes who were treated operatively versus nonoperatively according to the following classification system: nonoperative management for stage I injuries (nondisplaced) and anatomical reduction with fixation of stage II (diastasis with no arch height loss) and stage III (diastasis with arch height loss) injuries. Excellent outcomes were reported in 93% of their patients. They concluded that weight-bearing radiographs and bone scintigrams are sensitive, reproducible and relatively inexpensive methods to investigate this injury. Anatomic alignment was the key to excellent functional outcomes. (Level IV evidence)

Shaffer PT, Shaffer MA, Okereke E, et al: Effects of immobilization on plantar-flexion torque, fatigue resistance and functional ability following an ankle fracture. *Phys Ther* 80:769–780, 2000.

Study to investigate the effects of 8 weeks of immobilization on plantarflexion peak torque, fatigue resistance and functional ability (walking, stairs). They found decreased performance and functional ability after 8 weeks immobilization which can be reversed in 10 weeks of supervised physical therapy. (Level II evidence)

Shapiro MS, Wascher DC, Finerman GA: Rupture of Lisfranc's ligament in athletes. *Am J Sports Med* 22:687–691, 1994.

Nine athletes with Lisfranc ligament disruptions were presented in this retrospective review article. Nonoperative management was successful in returning the athletes back to competition in an average of 4 months. (Level III evidence)

Wadsworth DJ, Eadie NT: Conservative management of subtle Lisfranc Injury: A case report. *J Orthop Sports Phys Ther* 35: 154–164, 2005.

This is a case report that outlines the rehabilitation of a grade 1 Lisfranc injury in a 21-year-old professional basketball player. The authors report successful treatment included restricted activities, orthotic management, normalization of gait pattern, proprioceptive retraining, taping, and graduated return to sport. The athlete returned to sport 12 weeks post injury. Two year follow-up found no symptoms or restrictions in sport performance. (Level IV evidence)

Watson TS, Shurnas PS, Denker J: Treatment of Lisfranc joint injury: Current concepts. *J Am Acad Orthop* 18:718–728, 2010.

This review article summarizes the current concepts associated with Lisfranc injuries. It details the anatomy, mechanisms of injury, classifications, and diagnosis and nonoperative and operative management. (Level V evidence)

Multiple Choice Questions

QUESTION 1. What are common mechanisms of injury for a Lisfranc injury?

A. Axial longitudinal force sustained while the foot is plantarflexed and slightly rotated
B. Forced dorsiflexion
C. External rotation—stirrup
D. Internal rotation
E. Both a and c

QUESTION 2. When can an athlete return to sports after a stage I Lisfranc injury?

A. 12 weeks
B. 2 to 4 weeks
C. 5 to 7 weeks
D. 6 months

QUESTION 3. An example of strengthening for foot intrinsic muscles is:

A. aquatic therapy running
B. plyometrics
C. toe curls/scrunches
D. peroneal strengthening with Thera-Band.

QUESTION 4. Choose the best way to avoid placing a fulcrum over the midfoot during calf stretching.

A. In long sitting, wrap the stretching strap over the metatarsal heads instead of the midfoot
B. Stretch the soleus more than the gastrocnemius
C. In standing, place the involved foot behind with knee extended
D. Keep the subtalar joint in neutral during the calf stretch

Answer Key

QUESTION 1. Correct answer: **E** (see Introduction)

QUESTION 2. Correct answer: **A** (see Phase III)

QUESTION 3. Correct answer: **C** (see Phase II)

QUESTION 4. Correct answer: **C** (see Phase II)

POSTOPERATIVE REHABILITATION OF MIDFOOT SPRAINS (STAGE II-III LIGAMENTOUS LISFRANC INJURIES)

Eric R. Schweitzer, DPT, OCS, MTC, Lacy D. Jennings, DPT, SCS, MTC, Mark E. Easley, MD, and Jason M. Jennings, MD, DPT

Indications for Surgical Treatment

- Diastasis between the first and second metatarsals, based on weight-bearing radiographs.
- Asymmetry compared with contralateral foot.
- Failed nonoperative management of apparently stable Lisfranc injuries.
  - Empirically we have found that open reduction and internal fixation (in lieu of tarsometatarsal arthrodesis) may still be feasible up to 4 to 6 months postinjury.

Brief Summary of Surgical Technique

Percutaneous Fixation for Isolated Stage II and III Lisfranc Injuries

- Supine position with calf tourniquet
- Fluoroscopic guidance
- Pointed reduction clamp for reduction with the points positioned at the lateral aspect of the base of the second metatarsal and the medial aspect of the cuneiform (Figure 43-13)
- If the joint is anatomically reduced, a fully threaded percutaneous 3.5-mm screw is placed from the medial cuneiform to the base of the second metatarsal (Figure 43-14)
- If anatomical reduction is not possible via percutaneous attempts, convert to an open approach.

FIGURE 43-13. In the authors' preferred technique of percutaneous reduction, a large, pointed reduction clamp is used. *(From DeOrio M, Erickson M, Usuelli FG, Easley M: Lisfranc injuries in sport.* Foot Ankle Clin North Am *14:169–186, 2009, Figure 3, with permission.)*

FIGURE 43-14. Anteroposterior radiograph demonstrating complete reduction of the diastasis in a collegiate lacrosse player. *(From DeOrio M, Erickson M, Usuelli FG, Easley M: Lisfranc injuries in sport.* Foot Ankle Clin North Am *14:169–186, 2009, Figure 9, with permission.)*

FIGURE 43-15. K-wires are used to assist with provisional fixation. *(From DeOrio M, Erickson M, Usuelli FG, Easley M: Lisfranc injuries in sport.* Foot Ankle Clin North Am *14:169–186, 2009, Figure 6, with permission.)*

Open Reduction Internal Fixation for Isolated Stage II and III Lisfranc Injuries

- The joint is exposed through the interval between the extensor hallucis longus tendon and the deep neurovascular bundle located immediately deep to the extensor hallucis brevis tendon.
- The dorsal interosseous ligaments will be visibly torn.
- Rongeur to remove tissue deep within articulation between the medial cuneiform and the base of the second metatarsal, allowing anatomical reduction with a pointed reduction clamp per the preceding.
- Use K-wires for provisional fixation (Figure 43-15).
- Once anatomical reduction achieved, place a guide wire from the medial cuneiform to the base of the second metatarsal.
- The authors recommend making a 1- to 2-cm incision for placing this guide pin to retract the tibialis anterior tendon to be certain it is not injured during drilling and screw insertion.
- A cannulated drill is used over the guide pin.
- Although the authors use a cannulated drill system to create the drill hole, they prefer to use a stronger solid screw for fixation.
- An appropriate-length screw is advanced from the medial cuneiform to the base of the second metatarsal.

Factors That May Affect Details of Rehabilitation

- Plate fixation that spans the affected joints without violating the articular surfaces may minimize additional iatrogenic trauma. This may allow for earlier postoperative range of motion.
- Although the authors prefer open reduction and internal fixation (ORIF) over arthrodesis, purely ligamentous injuries or severely comminuted fracture-dislocations may have better outcomes if treated with arthrodesis.

Phase I (postoperative weeks 1 to 2)

Goals

- Protect the healing tissue.
- Control pain and swelling.
- Minimize the effects of immobilization.

Clinical Pearl

> Encourage activities that do not stress the healing tissues but still allow the athlete to move his/her proximal tissues (i.e., core and contralateral lower and bilateral upper extremity activities).

Protection

- Strict non–weight bearing (NWB) with crutches
- The authors typically place postoperative patients in a controlled ankle motion (CAM) walker (worn at all times) with the ankle in neutral dorsiflexion. If compliance is in question, then the patient is placed in a short leg cast.

Treatment of Pain and Inflammation

- Elevate lower leg above heart level
- Ice
- Modalities (electrical stimulation)
- ACE wrap/compression
- Nonsteroidal anti-inflammatory drugs (NSAIDs) and oral narcotics as needed

Techniques for Progressive Increase in Range of Motion

Stretching/Flexibility Techniques for the Musculotendinous Unit

- NWB: lower kinetic chain stretching as needed. No active or passive stretching of muscles crossing the foot and/or ankle

Other Therapeutic Exercises

- The athlete is encouraged to continue with core abdominal exercises and upper and contralateral lower extremity strengthening.
- Upper body ergometer (UBE) is utilized for cardiovascular fitness.

Sensorimotor Exercises

- Contralateral limb proprioceptive training including single leg balance

Milestones/Criterion-Based Rehabilitation Guidelines to Progress to the Next Phase

- Stable postoperative radiographs

Phase II (postoperative weeks 2 to 6)

Goals

- Protect the healing tissue.
- Control pain and swelling.
- Minimize the effects of immobilization.
- Stable radiographs week 6

Protection

- NWB with CAM walker or cast
- Crutches

Treatment for Pain/Analgesia

- NSAIDs

Treatment to Decrease Swelling

- Lower leg elevation above heart level
- Ice
- Modalities (electrical stimulation)
- ACE wrap/compression

Techniques for Progressive Increase in Range of Motion

Stretching/Flexibility Techniques for the Musculotendinous Unit

- Continue as per Phase I

Other Therapeutic Exercises

- Continue as per Phase I

Milestones/Criterion-Based Rehabilitation Guidelines to Progress to the Next Phase

- Stable postoperative radiographs

Phase III (postoperative weeks 6 to 10)

Goals

- Protect the healing tissue.
- Control pain and swelling.
- Minimize the effects of immobilization.
- Stable weight-bearing radiographs week 10

Protection

- NWB in a CAM walker
- If the patient was previously in a cast, then this is transitioned to a CAM walker.

Treatment for Pain/Analgesia

- Continue with selective modalities as needed (i.e., ice and electrical stimulation).
- NSAIDs as needed

Treatment to Decrease Swelling

- Continue with ice and elevation as in Phases I and II
- Ankle pumps, circles, ABCs

Techniques for Progressive Increase in Range of Motion

Soft Tissue Techniques

- Gentle techniques that help with reducing edema and mobilizing scar tissue once soft tissue scar healing has occurred

Stretching/Flexibility Techniques for the Musculotendinous Unit

- Continue as per phases I and II
- Gentle ankle and toe range of motion (ROM) at 6 weeks

Other Therapeutic Exercises

- Continue as per Phases I and II

Milestones/Criterion-Based Rehabilitation Guidelines to Progress to the Next Phase

- Stable weight-bearing postoperative radiographs

Phase IV (postoperative weeks 10 to 14)

Goals

- Protect the healing tissue: gradual transfer into partial weight bearing (PWB) followed by full weight bearing (FWB) with a custom orthotic and a stiff-soled shoe.
- Gradual restoration of gastrocnemius/soleus muscle length
- Initiate ankle/foot therapeutic exercises for strengthening and dynamic stability.
- Begin restoration of ankle/foot proprioception.

Clinical Pearl

- Gradually progress from PWB to FWB using a stiff-soled shoe and custom orthotic as well as taping as needed.
- Avoid passive towel stretches to gastrocnemius/soleus to avoid placing a fulcrum at the Lisfranc joint.

Protection

- Begin PWB (one-third body weight) in CAM walker at postoperative week 10
- PWB (two-thirds body weight) in CAM walker postoperative week 11
- FWB in a stiff-soled shoe with a custom orthotic postoperative week 12
- Midfoot taping may assist in plantarflexion of first ray, which helps to stabilize forefoot and support longitudinal arch in beginning stages of gait and functional training. Taping is not initiated until adequate soft tissue healing (scar) has occurred (see Figure 43-5).

Treatment for Pain/Analgesia

- NSAIDs as needed
- If significant pain is a limiting factor, return to physician for evaluation.
- Ice and modalities as needed

Treatment to Decrease Swelling

- Ice
- Compression
- Elevation

TIMELINE 43-2: **Postoperative Rehabilitation of Stage II to III Ligamentous Lisfranc Injuries**

PHASE I (weeks 1 to 2)	PHASE II (weeks 2 to 6)	PHASE III (weeks 6 to 10)
• NWB • CAM walker (cast for noncompliant patients) • PRICE and NSAIDs for inflammation	• NWB • CAM walker • Radiographs week 6	• NWB • CAM walker • If previously in a cast, then this is transitioned to a CAM walker • Gentle ankle and toe ROM • Weight-bearing radiographs week 10

- Ankle pumps, circles, ABCs
- Progressive weight bearing

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- No joint mobilizations due to emphasis on stabilization of the midfoot
- May perform talocrural joint mobilizations as needed to gain ankle joint mobility

Soft Tissue Techniques

- Gentle techniques that help with reducing edema and mobilizing scar tissue (respect soft tissue healing)

Stretching/Flexibility Techniques for the Musculotendinous Unit

- Gastrocnemius/soleus complex stretching with care not to create a fulcrum across midfoot region (recommend standing gastrocnemius wall stretch and weight bearing lunge stretch over long sitting towel stretch) (see Figure 43-6)
- Continue with proximal musculature stretching as needed

Other Therapeutic Exercises

- Begin aquatic therapy regimen—basic progressions as follows:
  - Shoulder → waist deep water
  - Double leg → single leg exercises
- Progress upper and lower extremity and core exercises as the athlete tolerates

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Intrinsic foot exercises starting at postoperative weeks 10 to 12
  - Towel scrunches/marble grabs
  - Intrinsic foot muscle strengthening (see Figure 43-7)
  - Isometric contraction of the first metatarsal head into the ground for peroneus longus strengthening (see Figure 43-9)
  - Intrinsic toe flexors isolation by contracting the extensor hallices longus to inhibit the ability of the long toe flexors to contract (see Figure 43-8)
- Gastrocnemius and soleus
  - Concentric progressing to eccentric
  - Retrain at heel strike to decelerate tibial internal rotation and control the lower limb moving over the foot

TIMELINE 43-2 **Postoperative Rehabilitation of Stage II to III Ligamentous Lisfranc Injuries** (Continued)

PHASE IV (weeks 10 to 14)

- Begin PWB (1/3 body weight) in CAM walker at postoperative week 10
- PWB (2/3 body weight) in CAM walker postoperative week 11
- FWB in stiff-soled shoe with custom orthotic
- Avoid fulcrum type force across the Lisfranc joint with stretching (i.e. towel stretch and strengthening)
- Talocrural mobilizations as needed to gain full ankle ROM
- Scar tissue mobilizations
- Intrinsic foot strengthening
- Extrinsic foot strengthening
- OKC/CKC progressions
  - Submaximal → maximal intensity
  - Short arc → full arc
  - Isometric → concentric → eccentric
- Aquatic therapy progressions
  - Shoulder → waist deep water
  - Double leg → single leg exercises
- Proprioception progressions
  - Sitting → standing
  - Partial weight-bearing → full weight-bearing
  - Double leg exercise → single leg exercise
  - Eyes open → eyes closed
- Gait training (aquatic → land)

PHASE V (weeks 14 to 24)

- Weight-bearing radiographs week 16 and 20
- Continued use of custom orthotic and stiff-soled shoe
- Begin running 20 weeks (aquatic → land) after hardware removal
- Aquatic therapy progression
  - Hop → jump
  - Fast walk → jog → run
- Continued proprioceptive progressions
  - Level surface → uneven surface
  - Shoes on → shoes off
  - Perturbations
  - Submaximal → maximal
  - Slow → fast
  - Known (proactive) → unknown (reactive) patterns
- Plyometrics
  - Aquatic → land
  - Bilateral → single leg
  - Jumping in place → forward, backward, and lateral over tape
  - Flat ground → small box (2-inch) gradually increasing the size as needed for particular sport
  - One plane of movement (frontal) → multiple planes of movement (frontal and transverse) → sport-specific drills
- Sport-specific activity at 20 weeks—after hardware removal
- Aquatic → land
- Jogging → running → sprints
- In-line activity → cutting
- Wide arching → tighter sharp turns
- Slow → fast
- Flat surface → uneven surface
- Known → unknown game situations

PHASE VI (weeks 24 to 52)

- Weight-bearing radiographs week 24
- If no evidence of reduction loss may return to full unrestricted athletics with the use of custom orthotic and a stiff-soled shoe

  - Controlled pronation by gastrocnemius and soleus allows forces to disperse to avoid excessive loading on individual tissues
- Posterior tibialis
  - Supination and inversion turns the foot into a rigid lever for push off. These actions also assist with stabilization of the midtarsal joints in stance phase.
  - The broad insertion of the posterior tibialis tendon plantar supports the transverse arch.[2]
- Peroneus longus
  - Supports the transverse arch in the late stage midstance and early heel off
  - Primary function is plantarflexion of the first ray
  - It is the primary stabilizer of the first ray.[1]
  - Assists with the transfer of body weight from the lateral to the medial side of the foot by everting the foot.[2]

Sensorimotor Exercises

- Per weight-bearing restrictions, progress week by week until able to fully bear weight
  - Proprioception progressions: Particular exercises are selected based on the athlete's stage and progression. Begin gentle and progress with objectively demonstrated tolerance:
    - Sitting → standing
    - Partial weight bearing → full weight bearing
    - Double leg exercise → single leg exercise
    - Eyes opened → eyes closed

Open and Closed Kinetic Chain Exercises

- Progress per weight-bearing status: use crutches or assistance with PWB and progress to FWB.
  - Principles of therapeutic exercise parameter progressions are based on the athlete's progress. Refer to the muscle activation section for specific exercises.
    - Submaximal → maximal intensity
    - Short arc → full arc
    - Isometric → concentric → eccentric
    - OKC exercises:
      - Plantarflexion (gastrocnemius/soleus)
      - Dorsiflexion (tibialis anterior)
      - Inversion (tibialis posterior)
      - Eversion (peroneal longus/brevis)
    - CKC exercises:
      - Heel raises (gastrocnemius/soleus)
      - Exercises using an unstable surface (see Figure 43-11)
      - Kinetic chain exercises (see Figure 43-12)

Techniques to Increase Muscle Strength, Power, and Endurance

- Per OKC/CKC progressions
- Bike, UBE, elliptical

Milestones/Criterion-Based Rehabilitation Guidelines to Progress to the Next Phase

- Stable postoperative radiographs
- Normal ROM, flexibility, and strength
- Minimal pain with FWB
- Normalizing gait

Phase V (postoperative weeks 14 to 24)

Goals

- Progression of proprioceptive and therapeutic exercise from Phase IV
- Stable weight-bearing radiographs weeks 16, 20, and 24
- Initiate plyometrics after hardware removal
- Begin sport-specific drills after hardware removal
- Initiate return to running program after hardware removal

Protection

- Assessment of footwear (i.e., cleats and stirrup)
- Assessment of field as related to footwear (i.e., natural grass vs. artificial turf)
- A stiff-soled shoe should be worn to provide midfoot stability.
- Continued use of custom orthotics

Treatment for Pain/Analgesia

- Ice and modalities as needed
- NSAIDs as needed

Techniques to Decrease Swelling

- Ice and modalities as needed

Techniques for Progressive Increase in Range of Motion

Manual Therapy Techniques

- As per Phase IV

Soft Tissue Techniques

- As per Phase IV

Stretching/Flexibility Techniques for the Musculotendinous Unit

- As per Phase IV

Other Therapeutic Exercises

- We typically will not progress to the higher-intensity aquatic therapy progressions below until after hardware removal at 20 weeks:
  - Hop → jump
  - Fast walk → jog → run
- Progress upper and lower extremity and core exercises as the athlete tolerates.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

Continue with exercises in Phase IV, progress as tolerated

BOX 43-1 Gradual Return to Running Program

Guidelines

1. Do every other day only (i.e., do not run daily).
2. Use running shoes when running (not court or cross trainers).
3. Begin at an easy pace on level surfaces, no hills.
4. Stop if you experience increasing excessive pain, swelling or stiffness, especially the next morning.
5. Try the phase at least twice. Progress to next phase if no increased pain, swelling or stiffness.
6. After Phase VIII: gradually increase your running without walking.

Phase I: Walk 2 miles at your own pace.

Phase II: Progress to walking 2 miles in 35 minutes.

Phase III (miles)	Walk 1/4	Run 1/4	Walk 1/4	Run 1/4				
Phase IV (miles)	Walk 1/4	Run 1/4	Walk 1/4	Run 1/4	Walk 1/4	Run 1/4	Walk 1/4	Run 1/4
Phase V (miles)	Walk 1/4	Run 1/2	Walk 1/4	Run 1/2	Walk 1/4	Run 1/2		
Phase VI (miles)	Walk 1/4	Run 3/4	Walk 1/4	Run 3/4				
Phase VII (miles)	Walk 1/4	Run 1	Walk 1/4	Run 1				

Sensorimotor Exercises

- Continue per Phase IV with advancement of proprioceptive progressions:
  - Level surface → uneven surface
  - Shoes on → shoes off
  - Perturbations
    - Submaximal → maximal
    - Slow → fast
    - Known (proactive) → unknown (reactive) patterns

Open and Closed Kinetic Chain Exercises

- Progress as per Phase IV

Techniques to Increase Muscle Strength, Power, and Endurance

- Progress as per Phase IV

Neuromuscular Dynamic Stability Exercises

- Progress as per Phase IV

Plyometrics

- Begin after removal of hardware (≈20 weeks).
- Initial plyometric type exercises are started in aquatic therapy (i.e., hop, jump).
- Progressions are slow, controlled, and advanced when the athlete demonstrates completion of a specific drill without compensation.
  - Bilateral → single leg
  - Jumping in place → forward, backward, and lateral over tape.
  - Flat ground → small (2-inch) box gradually increasing the size as needed for particular sport.
  - One plane of movement (frontal) → multiple planes of movement (frontal and transverse) → sport-specific drills

Functional Exercises

- Intertwine exercise principles from above with sport-specific movements (see Figure 43-10)

Sport-Specific Exercises

- We begin jogging/running after hardware removal at approximately week 20. Initiating a running program before hardware removal places the athlete at risk for subsequent hardware failure and/or loss of reduction. Running is initiated with aquatic therapy with the transition to land as the athlete tolerates. The return to running program we utilize is outlined in Box 43-1.
- Sport-specific activity such as cutting drills may begin after hardware removal at 5 months. Typically, secondary to the immediate postoperative period this occurs at around 5½ months.
- Return to sport is allowed at 6 months, but this will vary depending on the particular sport. Here are the general guidelines for progression in a pain-free (or minimal pain) manner.
  - Aquatic → land
  - Jogging → running → sprints
  - In-line activity → cutting
    - Wide arching → tighter sharp turns
    - Slow → fast
  - Flat surface → uneven surface
  - Known → unknown game situations

Milestones/Criterion-Based Rehabilitation Guidelines to Progress to the Next Phase

- Stable postoperative radiographs (weight-bearing) weeks 16, 20, 24
- The athlete may return to sport if he or she meets the return to sport criteria (see the following); otherwise, selective rehabilitation is continued.

Phase VI (postoperative weeks 24 to 52)

Goals

- Stable weight-bearing radiographs week 24
- Return to sport based on radiographs and physical performance during sport-specific training.
- Continue with progressions from Phase V

Protection

- Continued use of custom orthotic and stiff-soled shoe

Techniques for Progressive Increase in Range of Motion

Stretching/Flexibility Techniques for the Musculotendinous Unit

- Continue flexibility throughout lower extremity as needed

Other Therapeutic Exercises

- Continue as per Phase V

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Continue as per Phase V

Sensorimotor Exercises

- Continue as per Phase V

Open and Closed Kinetic Chain Exercises

- Continue as per Phase V

Techniques to Increase Muscle Strength, Power, and Endurance

- Continue as per Phase V

Neuromuscular Dynamic Stability Exercises

- Continue as per Phase V

Plyometrics

- Continue as per Phase V

Functional Exercises

- Continue as per Phase V

Sport-Specific Exercises

- Continue as per Phase V

Criteria for Return to Sport

- Stable postoperative radiographs
  - Weight-bearing radiographs with no loss of reduction
- Appropriate protective footwear
  - Custom orthotic
  - Stiff-soled shoe
  - Assessment of footwear (i.e., cleats)
  - Assessment of field as related to footwear (i.e., natural grass vs. artificial turf)
- Able to perform sports-specific drills
  - In our experience, the athlete will still experience some discomfort in the area of the Lisfranc complex initially, but this usually resolves with time.
- Specific criteria for return to sport are analyzed by the rehabilitation specialist for each athlete. The athlete is thoroughly tested to assure readiness for return to preinjury levels of activity.

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Sport-specific fitness and lower kinetic chain exercises

Exercises and Other Techniques for Prevention of Recurrent Injury (see Box 43-1)

- Custom orthotics
- Stiff-soled shoe
- Assessment of footwear (i.e., cleats)
- Assessment of field as related to footwear (i.e., natural grass vs. artificial turf)

Evidence

Chin L, Hertel J: Rehabilitation of ankle and foot injuries in athletes. *Clin Sports Med* 29:57–167, 2010.

This article details the general principles associated with rehabilitation of ankle and foot injuries in the athlete. Many of the therapeutic exercises and other treatments proposed for common foot/ankle injuries can be applied to midfoot sprains. (Level V evidence)

Curtis MJ, Myerson M, Szura B: Tarsometatarsal joint injuries in the athlete. *Am J Sports Med* 21:497–502, 1993.

This study was a retrospective review of 19 patients who injured the tarsometatarsal joint complex during athletic competition. Stress fluoroscopy of the articulation under anesthesia was used to supplement clinical and radiographic examination. Poor functional results were seen in those in whom diagnosis was delayed and inadequately treated unstable injuries with nonoperative immobilization. (Level III evidence)

DeOrio M, Erickson M, Usuelli FG, et al: Lisfranc injuries in sport. *Foot Ankle Clin North Am* 14:169–186, 2009.

This article reviews anatomy, classification, diagnosis, and treatment of Lisfranc injuries in sport. In addition, the authors' preferred operative technique is discussed in detail. (Level V evidence)

McKeon PO, Hertel J: Systematic review of postural control and lateral ankle instability, part II: Is balance training clinically effective? *J Athl Train* 43(3):305–315, 2008.

This study is a systematic review to see if prophylactic balance and coordination training can reduce risk of lateral ankle sprains, improve treatment outcomes associated with acute lateral ankle sprains, and improve outcomes in patients with chronic ankle instability. This study showed that balance

training can be used prophylactically or after acute ankle strains to help reduce further ankle sprains, but unable to determine the effectiveness with outcomes of chronic ankle sprains. (Level IV evidence)

Meyer SA, Callaghan JJ, Albright JP, et al: Midfoot sprains in collegiate football players. *Am J Sports Med* 22:392–401, 1994.

This retrospective study of 23 collegiate football players demonstrated an incidence of 4% of football players per year, with 29.2% of these players offensive lineman. The patients were followed for a mean of 30.8 months and most, despite a prolonged restriction from activity, reported minor residual problems. (Level III evidence)

Myerson MS, Cerrato RA: Current management of tarsometatarsal injuries in the athlete. *J Bone Joint Surg* 90-A:2521–2533, 2008.

This instructional course lecture presents the anatomy, clinical presentation, diagnostic imaging, and nonoperative and operative management of tarsometatarsal injuries in the athlete. (Level V evidence)

Nunley JA, Vertullo CJ: Classification, investigation, and management of midfoot sprains. Lisfranc injuries in the athlete. *Am J Sports Med* 30(6):871–878, 2002.

This retrospective cohort study used weight-bearing radiographs and bone scintigrams to diagnose Lisfranc injuries in 15 athletes who were treated operatively versus nonoperatively according to the following classification system: nonoperative management for stage I injuries (nondisplaced) and anatomical reduction with fixation of stage II (diastasis with no arch height loss) and stage III (diastasis with arch height loss) injuries. Excellent outcomes were reported in 93% of their patients. They concluded that weight-bearing radiographs and bone scintigrams are sensitive, reproducible, and relatively inexpensive methods to investigate this injury. Anatomic alignment was the key to excellent functional outcomes. (Level IV evidence)

Shaffer PT, Shaffer MA, Okereke E, et al: Effects of immobilization on plantar-flexion torque, fatigue resistance and functional ability following an ankle fracture. *Phys Ther* 80:769–780, 2000.

Study to investigate the effects of 8 weeks of immobilization on plantarflexion peak torque, fatigue resistance, and functional ability (walking, stairs). They found decreased performance and functional ability after 8 weeks immobilization which can be reversed in 10 weeks of supervised physical therapy. (Level II evidence)

Shapiro MS, Wascher DC, Finerman GA: Rupture of Lisfranc's ligament in athletes. *Am J Sports Med* 22:687–691, 1994.

Nine athletes with Lisfranc ligament disruptions were presented in this retrospective review article. Nonoperative management was successful in returning the athletes back to competition in an average of 4 months. (Level IV evidence)

Wadsworth DJ, Eadie NT: Conservative management of subtle Lisfranc injury: A case report. *J Orthop Sports Phys Ther* 35: 154–164, 2005.

This is a case report that outlines the rehabilitation of a grade 1 Lisfranc injury in a 21-year-old professional basketball player. The authors report successful treatment included restricted activities, orthotic management, normalization of gait pattern, proprioceptive retraining, taping, and graduated return to sport. The athlete returned to sport 12 weeks post injury. Two-year follow-up found no symptoms or restrictions in sport performance. (Level IV evidence)

Watson, TS, Shurnas PS, Denker J: Treatment of Lisfranc joint injury: Current concepts. *J Am Acad Orthop* 18:718–728, 2010.

This review article summarizes the current concepts associated with Lisfranc injuries. It details the anatomy, mechanisms of injury, classifications, and diagnosis and nonoperative and operative management. (Level V evidence)

Multiple Choice Questions

QUESTION 1. Which of the following is an example of strengthening for foot intrinsic muscles?

A. Aquatic therapy running
B. Plyometrics
C. Toe curls/scrunches
D. Peroneal strengthening with Thera-Band

QUESTION 2. Which of the following is the best type of footwear for the athlete once he or she is cleared to return to sport?

A. Cushioned shoe
B. Motion control shoe with off-the-shelf orthotic
C. Stiff-soled sole with custom orthotic
D. Any type of shoe with midfoot taping technique

QUESTION 3. When is it appropriate to start plyometric/jumping activities after surgery?

A. Once athlete is able to fully weight-bear
B. After hardware removal, approximately 5 to 6 months
C. Before hardware removal around 4 months
D. Once athlete has no pain and swelling

QUESTION 4. Postoperatively, patients are placed in a CAM walker (worn at all times) with the ankle in what position?

A. Neutral dorsiflexion
B. Relaxed plantarflexion
C. Slight inversion
D. Calcaneal eversion

Answer Key

QUESTION 1. Correct answer: **C** (see Phase IV)

QUESTION 2. Correct answer: **C** (see Criteria for Return to Sport)

QUESTION 3. Correct answer: **B** (see Phase V)

QUESTION 4. Correct answer: **A** (see Phase I)

Chapter 44

Fifth Metatarsal Fractures

INTRODUCTION

Timothy S. Mologne, MD

Epidemiology

- Fractures of the fifth metatarsal are relatively common in athletic individuals.
- There is no association with age or sex, but they are more common in athletes who participate in cutting type sports, particularly basketball and football players. They are also seen in female dancers.

Pathophysiology

Intrinsic Factors

- Fractures at the base of the fifth metatarsal can result from an inversion injury, with resultant avulsion of the peroneal brevis tendon or plantar aponeurosis. The injury mechanism is similar to that seen with an acute lateral ankle sprain.
- Fractures of the middle and distal diaphysis commonly involve a fall on a plantarflexed and inverted foot. This mechanism is often seen in dancers.
- Fractures of the proximal fifth metatarsal distal to the tuberosity (Jones fracture) usually occur from a vertical oriented force, a medial-lateral force, or a combination of the two as the patient raises the heel and puts pressure on the metatarsal head.
- There are strong stabilizing ligaments between the base of the fifth metatarsal and the cuboid and fourth metatarsal. These ligaments and the capsular attachments help to stabilize the fifth metatarsal and result in force concentration to the fifth metatarsal just distal to the articulation with the fourth metatarsal.
- A varus hindfoot has been associated with fifth metatarsal Jones fractures.[1]

Traumatic Factors

- Dancer's fracture
- Inversion injury and styloid avulsion
- Vertical/medial-lateral force as the heel is raised

Classic Pathological Findings

- Fractures of the fifth metatarsal can be divided into shaft and neck fractures, styloid fractures, and fractures at the metadiaphyseal junction—the so-called Jones fracture.
- Stress fractures at the metadiaphyseal junction can results in cortical hypertrophy, periosteal new bone formation, and widening at the fracture site.
- Nonunions can also be seen, with intramedullary sclerosis.

Clinical Presentation

History

- A thorough evaluation of the patient's history may help distinguish a stress fracture from an acute fracture.
- Prodromal pain at the site of the fracture prior to an acute injury might signify a stress type fracture.
- Patients often report a twisting injury to the ankle or an inversion injury to the foot.
- Patients with acute fractures usually have difficulty ambulating or applying pressure on the affected foot.

Physical Examination

- Tenderness to palpation at the fracture site
- Accentuation of pain with foot inversion
- Occasional swelling and ecchymosis at the fracture site
- Difficulty bearing weight on the affected foot

Imaging

- An anteroposterior, oblique, and lateral radiograph of the affected foot are helpful in establishing a diagnosis.
- A styloid fracture should be assessed for displacement and comminution (Figure 44-1)

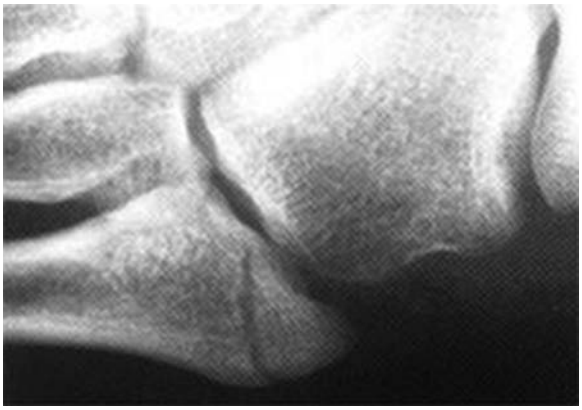

FIGURE 44-1. A nondisplaced styloid avulsion fracture.

- Fractures of the proximal fifth metatarsal distal to the tuberosity (Jones fracture) should be assessed for chronicity. Torg[2] classified Jones fractures as (1) acute fractures, (2) delayed unions, and (3) nonunions. The acute fracture was defined as a fracture with a sharp fracture line with no widening, no intramedullary sclerosis, and little to no cortical hypertrophy (Figure 44-2). The delayed union was defined as a fracture with a widened fracture line, a fracture involving both cortices and with a periosteal reaction, and some intramedullary sclerosis (Figure 44-3). The nonunion was defined as a fracture with a wide fracture line, periosteal new bone, and complete obliteration of the intramedullary canal with sclerotic bone (Figure 44-4).
- In skeletally immature patients, the base of the fifth metatarsal has an apophysis, which should not be confused for a fracture. The apophysis is parallel to the shaft of the metatarsal.

FIGURE 44-3. A delayed union Jones fracture with widening of the fracture line, and some intramedullary sclerosis.

Differential Diagnosis

- Fractures at the base of the fifth metatarsal can be mimicked by:
  - Fifth metatarsal apophysis in skeletally immature patients. The apophysis is parallel to the shaft and does not extend proximally into the fifth metatarsal-cuboid articulation.
  - Os peroneum. An ossicle in the peroneus longus tendon adjacent to the base of the fifth metatarsal. The ossicle is rounded as compared to an acute fracture.

FIGURE 44-2. An acute Jones fracture with a sharp fracture line, no widening, no periosteal reaction, and no cortical hypertrophy.

FIGURE 44-4. A nonunion of a Jones fracture with a widened fracture line and obliteration of the intramedullary canal with sclerotic bone.

Treatment

Nonoperative Management

- Styloid avulsion fractures have an excellent chance of successful treatment with conservative treatment. Treatments can vary with the size of the fracture fragment, displacement, and amount of comminution, and can include protective ambulation in a hard sole shoe, a firm last boot, a CAM walker, or a short leg walking cast.[3]
- Metatarsal shaft and neck fractures also have an excellent chance of successful treatment without surgery. Immobilization in a CAM walker or short leg walking cast for 4 to 6 weeks is common.[3]
- Jones fractures can be challenging to get to heal conservatively. Nonunions and refractures are common.[4] If conservative treatment is elected, a short leg non–weight-bearing cast for 6 to 8 weeks, followed by protected weight bearing until fracture union.[2,3]

Guidelines for Choosing Among Nonoperative Treatments

- In general, styloid avulsion fractures and shaft and neck fractures are treated conservatively.
- Acute Jones fractures can be successfully treated with nonsurgical treatment but can result in a lengthy recovery. Athletes may be less tolerant of prolonged immobilization, especially if there is a real probability of a refracture once they return to competitive sports.
- Conservative management of Jones fractures may be very dysfunctional for nonathletes, especially those who have difficulty ambulating with crutches and those who do not have the balance or upper body strength to ambulate non–weight-bearing on the affected limb.

Surgical Indications

- There are no absolute surgical indications.
- Widely displaced or angulated shaft fractures can be managed with open reduction and internal fixation.
- Large, displaced styloid fractures can also be managed with reduction and internal fixation.
- Although rare, symptomatic styloid fracture nonunions are also an indication for surgical intervention.
- Relative indications for surgical intervention include Jones fractures that are classified as delayed unions or nonunions at initial presentation; refractures; Jones fractures in athletes; and Jones fractures in individuals who are unwilling or unable to adhere to the 6 to 8 week non–weight-bearing guideline for conservative treatment.

Aspects of Clinical Decision Making When Surgery Is Indicated

- Size of the metatarsal and intramedullary canal will influence the size of screw used for fixation. Intramedullary screws smaller than 4.5 mm have been associated with a failure of surgery for Jones fractures (Figure 44-5).[5]

FIGURE 44-5. Successful union of a Jones fracture using an intramedullary 4.5-mm malleolar screw.

- For displaced and angulated shaft fractures, one must decide whether the fracture can be managed with interfragmentary screws, plate fixation, or a combination.

Evidence

Clapper M, O'Brien T, Lyons P: Fractures of the fifth metatarsal. *Clin Orthop* 315:238–241, 1995.

The authors reported on outcomes of treatment of 100 patients enrolled in a fifth metatarsal fracture registry. Styloid avulsion fractures healed without immobilization and shaft/neck fractures healed with weight-bearing casting. Jones fracture treated in a non–weight-bearing cast was only successful in 72% of the patients and the average time to healing in this successful group was 21 weeks. (Level 4 evidence)

Glasgow MT, Naranja RJ, Glasgow SG, et al: Analysis of failed surgical management of fractures of the base of the fifth metatarsal distal to the tuberosity: The Jones fracture. *Foot Ankle Int* 17(8):449–457, 1996.

This retrospective study reported on 11 patients who had failed screw fixation for a Jones fracture. Screw sizes less than 4.5 mm and an early return to vigorous physical activity correlated with delayed union and refracture. (Level 4 evidence)

Mologne TS, Lundeen J, Clapper M, et al: Early screw fixation versus casting in the treatment of acute Jones fractures. *Am J Sports Med* 33(7):970–975, 2005.

This prospective, randomized control study compared early screw fixation to casting in the treatment of acute Jones' fractures. Screw fixation was successful in 95% and allowed patients to return to running and jumping in 8 weeks. Cast treatment resulted in failure of treatment in 44%. In the successfully treated patients, the median time to return to running and jumping sports was 15 weeks. (Level 1 evidence)

Raikin SM, Slenker N, Ratigan B: The association of a varus hindfoot and fracture of the fifth metatarsal metaphyseal-diaphyseal junction: The Jones fracture. *Am J Sports Med* 36(7):1367–1372, 2008.

In this case series of 21 Jones fractures, the authors found hindfoot varus alignment by radiographic parameters in 86%. Based on this association, the authors have recommended a varus unloading orthotic insert to help prevent reinjury or refracture. (Level 4 evidence)

Torg J, Balduini F, Zelko R, et al: Fractures of the base of the fifth metatarsal distal to the tuberosity. *J Bone and Joint Surg* 66A:209–214, 1984.

In this retrospective review, the authors described the outcomes of 46 Jones fractures. They defined the acute fracture, delayed union, and nonunion, and showed a 93% healing rate in acute fractures treated with non–weight-bearing short leg casting for 6 to 8 weeks. (Level 4 evidence)

Multiple-Choice Questions

QUESTION 1. Fractures of the middle and distal diaphysis commonly involve a fall on the

A. inverted foot.
B. plantarflexed foot.
C. plantarflexed and inverted foot.
D. plantarflexed and everted foot.

QUESTION 2. Which foot postural alignment is associated with a Jones fracture?

A. Hindfoot varus
B. Hindfoot valgus
C. Forefoot valgus
D. Forefoot varus

QUESTION 3. Stress fractures at the metadiaphyseal junction can result in

A. cortical hypertrophy.
B. periosteal new bone formation.
C. widening at the fracture site.
D. All of the above.

QUESTION 4. Immobilization in a CAM walker or short leg walking cast for metatarsal shaft and neck fractures should be done for

A. 10 weeks.
B. 4 to 6 weeks.
C. 2 to 3 weeks.
D. 10 to 12 weeks.

QUESTION 5. Jones fractures, if treated conservatively, should be in a short leg non–weight-bearing cast for

A. 6 to 8 weeks.
B. 2 weeks.
C. 10 to 12 weeks.
D. 4 to 6 weeks.

Answer Key

QUESTION 1. Correct answer: **C** (see Pathophysiology, Intrinsic Factors)

QUESTION 2. Correct answer: **A** (see Pathophysiology, Intrinsic Factors)

QUESTION 3. Correct answer: **C** (see Pathophysiology, Classic Pathological Findings)

QUESTION 4. Correct answer: **B** (see Treatment, Nonoperative Management)

QUESTION 5. Correct answer: **A** (see Treatment, Nonoperative Management)

NONOPERATIVE REHABILITATION OF FIFTH METATARSAL FRACTURES (INCLUDING JONES FRACTURE)

Brad McMahon, MPT, Laura Lundgren, PA-C, and Timothy S. Mologne, MD

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- Restore ankle and subtalar range of motion.
- Restore ankle and foot strength.
- Improve proprioception and balance.
- Protect the healing of the bone during the rehabilitation process.
- Maintain cardiovascular fitness throughout the rehabilitation process.
- Possibly improve mechanics and shoe wear to help prevent future injury.

Phase I (weeks 4 to 8 depending on the fracture site)

- In general, physical therapy is not initiated in the early phases of treatment of fifth metatarsal fractures.
- Cardiovascular fitness can be maintained by the use of an upper extremity bike and upper extremity workouts can be continued to maintain the fitness of the athlete.

Protection

- Fifth metatarsal shaft/neck fractures are managed in a walking cast or walking boot for 4 to 6 weeks. Immobilization is critical for fracture union, and as such, therapy, other than instruction and education in the proper use of crutches, is not indicated.
- Jones fractures are managed in a non–weight-bearing short leg cast for 6 to 8 weeks. Therapy other than crutch training is also not indicated in this phase.
- Styloid avulsion fractures can be managed in a protective boot or shoe, usually for 4 weeks because the ankle does not need to be immobilized.
- Bone stimulators (pulsed electromagnetic fields) have been shown to be effective in the management and healing of nonunions and delayed unions.[1]

Management of Pain and Swelling

- Pain can be managed with appropriate use of analgesics.
- Because nonsteroidal anti-inflammatory agents have been shown to delay bone healing, these are generally avoided for the first 6 weeks.
- Ice and electrical stimulation can also be used to manage pain and swelling.

Phase II (Shaft and neck fractures: weeks 4 to 6; styloid avulsion fractures, weeks 4; Jones fractures: weeks 8 to 16)

Protection

- Shaft and neck fractures should be nearly asymptomatic at 6 weeks.
- A firm last shoe can help to limit stress across the metatarsal.
- Patients with styloid avulsion fractures can usually resume regular shoe wear by 4 weeks.
- Patients with Jones fractures are managed in a removable CAM walker boot after the initial 6 to 8 weeks of non–weight-bearing immobilization.

TIMELINE 44-1: **Nonoperative Rehabilitation of Fifth Metatarsal Fracture**

PHASE I (weeks 4 to 8 depending on fracture site)	PHASE II (weeks 4 to 16)	PHASE III (weeks 8 to 16)
• Fifth metatarsal shaft/neck fractures in walking cast or walking boot for 4 to 6 weeks • Jones fractures in non-WB'ing short leg cast for 6 to 8 weeks • Styloid avulsion fractures in a protective boot or shoe for 4 weeks (ankle does not need to be immobilized). • Ice and pain meds as needed • Maintain cardiovascular fitness (upper extremity bike or upper extremity workouts)	• Fifth metatarsal shaft/neck fractures 4 to 6 weeks can be full weight bearing in firm last or hard-soled shoe • Jones fractures 8 to 16 weeks are managed in CAM walker boot • Styloid avulsion fractures 4 weeks can usually resume regular show wear. • Ankle ROM and plantar fascia stretching • Manual resistance exercises in all ankle planes • Start single leg balance and sensorimotor exercises. • Gait training with no gait deviations • Ice as needed for inflammation	• Fifth metatarsal shaft/neck fractures 10 to 12 weeks • Jones fractures 14 to 16 weeks • Styloid avulsion fractures 8 to 10 weeks • Attempt to get patient back to prior level of function • Patient should have full ankle ROM • Strengthening of foot and ankle continued • Single leg balance and proprioception exercises progressed • Dynamic reaction drills • Jumping and plyometrics added • Running and sport specific drills

FIGURE 44-6. Towel stretch for dorsiflexion ROM.

Management of Pain and Swelling

- Swelling is usually not present in this phase, but again can be managed with ice and electrical stimulation if needed.

Techniques for Progressive Increase in Range of Motion

- Prolonged immobilization can result in ankle stiffness, muscle weakness, ligamentous and fascial tightness, and disuse atrophy of the foot and leg muscles.
- Full range of motion needs to be achieved.
- Ankle range of motion exercises in all planes (dorsiflexion, plantar flexion, inversion and eversion)
  - Wall stretch, towel stretch, self-stretches with wobble boards or hand (Figure 44-6)
- Plantar fascia stretching
  - Rolling with a can or bottle (Figure 44-7)

FIGURE 44-7. Plantar fascia stretching with bottle.

FIGURE 44-8. Balance and proprioception rehabilitation using the biomechanical ankle platform system (BAPS).

Other Therapeutic Exercises

- Again, maintaining whole-body cardiovascular fitness is a main goal. Pool workouts, stationary bike, and stair climbers can all be used as an alternative to running.
- Core stability exercises and upper extremity strengthening can be continued.

Activation of Primary Muscles Involved

- Peroneals, gastrocnemius, soleus, tibialis anterior/posterior, toe extensors/flexors
  - Thera-Band ankle strengthening in all directions
  - Balance exercises (see the following)
  - Calf raises (knee extended/knee bent)
  - Towel pick-ups
  - Heel/toe walks

Sensorimotor Exercises

- Start with weight-shifting and progress to single leg balance.
- Single leg balance on wobble boards, Dyna Discs, trampoline, incline surfaces, biomechanical ankle platform system (BAPS) (Figure 44-8)

Open and Closed Kinetic Chain Exercises

- Thera-Band ankle strengthening in all directions, toe flexor/extensor exercises (towel pick-ups), heel raises, squats/lunges, hip strengthening with Thera-Band (Figure 44-9)

Neuromuscular Dynamic Stability Exercises

- Dynamic reaction drills on the trampoline and progression into ball toss and perturbations on balance boards (Figure 44-10).

FIGURE 44-9. Hip strengthening with Thera-Band.

- Standing single balance movement drills
- Slide board or Pro-fitter

Functional Exercises

- Will start with early weight shifting, gait training, and eventual walking with no gait deviations

Milestones for Progression to the Next Phase

- The patient's pain level over the fracture area dictates the level of activity or progression of stages.

FIGURE 44-10. Single balance on wobble boards.

- Absence of pain, full ankle range of motion, restoration of strength in the foot and ankle
- Evidence of union of the fracture on follow up radiographs

Phase III (weeks 10 to 12, shaft and neck fractures; weeks 8 to 10, styloid avulsion fractures; weeks 14 to 16 Jones fractures)

Management of Pain and Swelling

- Ice and electrical stimulation if needed.

Techniques for Progressive Increase in Range of Motion

- In this phase, we attempt to get the athlete and patient back to his or her preinjury level of function. This includes running and jumping sports.
- The patient should have full ankle and subtalar range of motion.
- Stretching techniques from Phase II can be continued for warm-up or cool-down before heavy work-out or sport practice.

Other Therapeutic Exercises

- Continued from Phase II

Activation of Primary Muscles Involved

- Peroneals, gastrocnemius, soleus, tibialis anterior/posterior, toe extensors/flexors
  - Thera-Band ankle strengthening in all directions
  - Balance exercises (see the following)
  - Calf raises (knee extended/knee bent)
  - Towel pick-ups
  - Heel/toe walks

Sensorimotor Exercises

- Continue with Phase II exercises.
- Progressing to Thera-Band resistance, ball toss, and perturbations

Open and Closed Kinetic Chain Exercises

- Continue with Phase II exercises.

Neuromuscular Dynamic Stability Exercises

- Continue with Phase II exercises.

Plyometrics

- Starting with double leg and progressing to single leg (Figure 44-11)
- Platform jumps, progressing height depending on difficulty

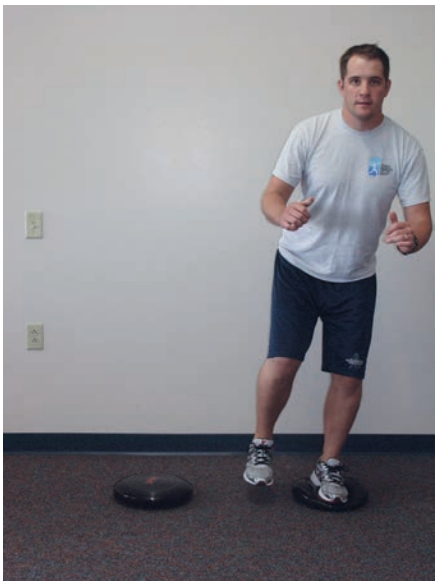

FIGURE 44-11. Single balance hopping progression exercise.

Functional Exercises

- Jogging to running with progression from straight forward to side to side and cutting agility drills

Sport-Specific Exercises

- Depending on the sport, cutting, twisting, pivoting, and other sport-related drills

Milestones for Progression to Advanced Sport-Specific Training and Conditioning

- The rehabilitation program needs to be individualized and adjusted for each athlete depending on the sport and the initial fracture site.
- Absence of pain, full ankle range of motion, restoration of strength in the foot and ankle
- Evidence of union of the fracture on follow-up radiographs

Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention

- Fifth metatarsal shaft and neck fractures, as well as styloid avulsion fractures are well managed conservatively. Successful union is nearly universal, and abandoning nonoperative treatment should not be necessary unless significant fracture displacement is noted on interval follow-up radiographs.
- Symptomatic fractures with evidence of nonunion by radiographs. For Jones fractures, union can take up to 21 weeks.[2]
- Patient reluctance or inability to adhere to the non–weight-bearing recommendations in the first phase

Performance Enhancement and Beyond Rehabilitation: Training/Trainer and Optimization of Athletic Performance

- Mechanism of jumping and running to prevent reinjury
- Proper shoe wear, possible use of orthotics or external support during competition
- Maintaining foot and ankle strength/ROM, balance, and proprioception

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Absence of pain, full ankle range of motion, restoration of strength in the foot and ankle
- Evidence of union of the fracture on follow-up radiographs

Evidence

Aaron RK, Ciombor DM, Simon BJ: Treatment of nonunions with electric and electromagnetic fields. *Clin Orthop Relat Res* (419):21–29, 2004.

This is a review article were the authors concluded that electric and electromagnetic fields had improved results in delayed and nonunion fractures compared with placebo treatment. (Level IV evidence)

Clapper MF, O'Brien TJ, Lyons PM: Fractures of the fifth metatarsal. Analysis of a fracture registry. *Clin Orthop Relat Res* 238–241, 1995.

In this article a fracture registry was established. The authors found that avulsion fractures healed with immobilization usually in 4 weeks, shaft/neck fractures healed in casts with WBAT in 4 to 6 weeks, and Jones fractures required a prolonged time to heal, on average 21.2 weeks. (Level IV evidence)

Collins KS, Streitz W: Bilateral Jones fractures in a high school football player. *J Athl Train* 31:253–256, 1996.

This is a case report that presented a high school football player with bilateral Jones fractures who was treated both conservatively and with a screw fixation. It is specific to football and shows the progression of both surgical and nonsurgical treatments. (Level IV evidence)

Holmes GB, Jr: Treatment of delayed unions and nonunions of the proximal fifth metatarsal with pulsed electromagnetic fields. *Foot Ankle Int* 15:552–556, 1994.

This study looked at nine delayed unions and nonunions of the proximal fifth metatarsal that were treated with pulsed electromagnetic fields and found that the mean time of fracture healing was 3 months compared with 4 months without the pulsed electromagnetic fields. (Level IV evidence)

Mologne TS, Lundeen JM, Clapper MF, et al: Early screw fixation versus casting in the treatment of acute Jones fracture. *Am J Sports Med* 33:970–975, 2005.

In this randomized controlled trial, 18 patients were randomized to cast treatment and 19 patients were randomized to screw fixation. The authors found that early screw fixation results in faster times to union and return to sport compared with cast treatment. (Level I evidence)

Multiple Choice Questions

QUESTION 1. Styloid avulsion fractures can be managed in a

A. CAM walker boot for 10 weeks.
B. short leg cast for 6 to 8 weeks.
C. protective boot or shoe, usually for 4 weeks.
D. CAM walker for 6 weeks.

QUESTION 2. For Jones fractures, radiographic union has been shown to take up to

A. 4 weeks.
B. 10 weeks.
C. 8 weeks.
D. 21 weeks.

QUESTION 3. Shaft and neck fractures should be nearly asymptomatic at

A. 6 weeks.
B. 10 weeks.
C. 16 weeks.
D. 2 weeks.

QUESTION 4. Activation of these primary muscles are important in the nonoperative rehabilitation of the Jones fracture?

A. Peroneals
B. Gastroc/soleus
C. Toe extensors/flexors
D. All of the above

QUESTION 5. The key milestone for progression to the next phase of the rehab process is from Phase II to Phase III is

A. the patient's pain level over the fracture site.
B. full ankle ROM.
C. evidence of union of the fracture on follow-up radiographs.
D. all of the above

Answer Key

QUESTION 1. Correct answer: **C** (see Phase I)

QUESTION 2. Correct answer: **D** (see Criteria for Abandoning Nonoperative Treatment and Proceeding to Surgery or More Intensive Intervention)

QUESTION 3. Correct answer: **A** (see Phase II)

QUESTION 4. Correct answer: **D** (see Phase II)

QUESTION 5. Correct answer: **D** (see Phase II)

POSTOPERATIVE REHABILITATION AFTER INTERNAL FIXATION OF FIFTH METATARSAL FRACTURES

Timothy S. Mologne, MD, Laura Lundgren, PA-C, and Brad McMahon, MPT

Indications for Surgical Treatment

- Acute Jones fracture in athletes
- Symptomatic delayed union or non-union Jones fracture
- Refractures
- Patients that are unwilling or unable to adhere to nonoperative treatment guidelines with non–weight-bearing immobilization

Brief Summary of Surgical Treatment

- Supine position with a bump under the ipsilateral hemipelvis
- Use of tourniquet not necessary but can be used per surgeon's choice
- Radiolucent table and use of fluoroscopy
- Anesthesia options per surgeon's choice, including regional block, spinal, local anesthesia with MAC, and general anesthesia
- A 1-cm longitudinal incision is made proximal to the base of the fifth metatarsal.
- The sural nerve is dorsal to the skin incision but blunt dissection to the base of the fifth metatarsal is recommended.
- A 3.2-mm drill guide is placed at the tip of the fifth metatarsal styloid. Fluoroscopy is used to assure the drill is centered on the tip.

- A 3.2-mm drill is then drilled through the intramedullary canal of the metatarsal and across the fracture. Fluoroscopy is also used to assure the drill is passing through the canal. The drill can be used as a "power sound," stopping the drill if the cortex is felt.
- The drill will eventually contact the dorsal and medial aspect of the distal portion of the metatarsal shaft, because the shaft is curved and not purely linear.
- The length of the drill canal can be measured with a depth gauge but is usually between a 55- and 65-mm screw.
- Various screw types have been used. We have not found it necessary to use a cannulated screw and use a 4.5-mm malleolar screw.
- Care must be made to assure that screw threads are distal to the fracture line.
- The screw can be countersunk to help keep it from being prominent.
- Fluoroscopy is used to assure the screw is properly placed and that the screw head is not prominent.
- The incision is then closed in layers and a sterile dressing is applied.
- Patients are placed in a CAM (controlled ankle motion) walker boot.

Before Surgery: Overview of Goals, Milestones, and Guidelines[1]

GUIDING PRINCIPLES OF POSTOPERATIVE REHABILITATION

- Achieve full foot and ankle ROM
- Restoration of strength in the foot/ankle and lower extremity
- Protect fracture site and healing of bone in each phase of the rehab process
- Maintain cardiovascular fitness

[1]Prehabilitation, if appropriate, is described in the Nonoperative Rehabilitation section of this chapter.

Phase I (days 0 to 14): Immediate Postoperative Period

Goals

- Protected weight bearing until the wound has healed
- Reduce swelling and pain with ice and medications
- Maintain ankle and subtalar joint motion
- Maintain cardiovascular fitness with arm bike
- Possible bone stimulator if ordered for delayed or nonunions

Protection

Patients use crutches and CAM walker boot. Once the sutures are removed, they can begin weight bearing as tolerated in a firm last boot, CAM walker boot, or hard sole shoe.

Management of Pain and Swelling

For Pain

- Pain following the surgery is usually quite minimal, and can be managed with acetaminophen and/or a mild oral narcotic for a few days. Ice is also used to help reduce pain.

For Swelling

- Ice can be used to help reduce swelling. However, as the surgery is done nearly percutaneously, swelling is usually minimal.

Techniques for Progressive Increase in Range of Motion

- Gentle ROM exercises can be done at the ankle: self-stretches with wobble boards or hand (Figures 44-12 and 44-13)

Other Therapeutic Exercises

- Again maintaining whole body cardiovascular fitness is a main goal. An arm bike can be used and the patient can continue with upper extremity strengthening, and core exercises maintain the weight-bearing status
- Usually at 3 to 5 days the patient may start stationary bicycle with a protective boot on.

TIMELINE 44-2: Postoperative Rehabilitation after Internal Fixation of Fifth Metatarsal Fractures

PHASE I (weeks 0 to 2)	PHASE II (weeks 2 to 6)	PHASE III (weeks 6 to 10)
• Protected weight bearing with CAM walker boot and crutches • Early and gentle ankle ROM • Ice and pain meds as needed • Maintain cardiovascular fitness (stationary bicycle)	• Full weight bearing in firm last or hard sole shoe • Continued ankle ROM and plantar fascia stretching • Ice as needed for swelling • Start single leg balance exercises • Manual resistance exercises in all ankle planes	• Foot orthotic still may be used with an external support • Full ankle ROM • Strengthening of foot and ankle with resistance bands • Single leg balance and proprioception exercises progressed • Dynamic reaction drills • Jumping and plyometrics added • Running and sport-specific drills

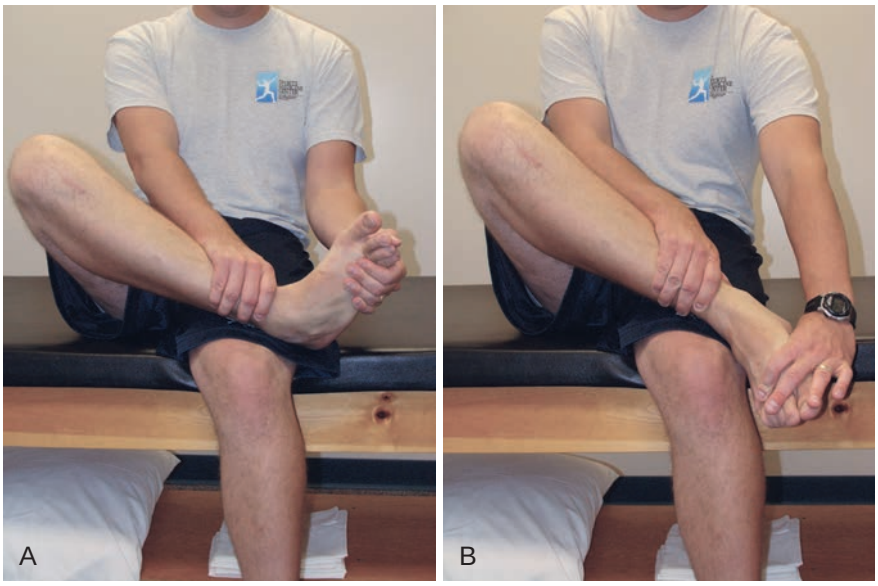

FIGURE 44-12. Self stretches for inversion and eversion.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Strengthening is not indicated at this time period.

Functional Exercises

- Gaiting training with crutches can be done to minimize gait deviations.

Milestones for Progression to the Next Phase

- Pain-free ambulation with protective boot

Phase II (weeks 2 to 6)

Clinical Pearls

Peroneus brevis tendon may be irritated from the surgical approach, so strengthening may need to be delayed until inflammation subsides. Other strengthening is usually tolerated without problems.

Goals

- Progression into weight bearing
- Reduce swelling and pain with ice and medications
- Maintain ankle and subtalar joint motion
- Maintain cardiovascular fitness with stationary bike now
- Continued bone stimulator if ordered.

Protection

- Progression into weight bearing so crutches may be discontinued as tolerated. Patient still may be wearing firm last shoe or hard sole shoe at this point if she or he is still having pain with walking.

Management of Pain and Swelling

For Pain

- Should be minimal at this point, but can be managed with acetaminophen and ice.

For Swelling

- Continued ice can be used to help reduce the swelling if any is present with the increase in weight bearing.

Techniques for Progressive Increase in Range of Motion

- Full range of motion needs to be achieved
- Ankle range of motion exercises in all planes (dorsiflexion, plantar flexion, inversion and eversion)
  - Wall stretch, towel stretch, self-stretches with wobble boards or hand

FIGURE 44-13. Wobble board PROM for inversion and eversion.

- Plantar fascia stretching
  - Rolling with a can or bottle

Other Therapeutic Exercises

- Again maintaining whole body cardiovascular fitness is a main goal. Pool workouts, stationary bike, and stair climbers can all be used as an alternative to running at this point.
- Core stability exercises and upper extremity strengthening can be continued.

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Peroneals, gastrocnemius, soleus, tibialis anterior/posterior, toe extensors/flexors
  - Thera-Band ankle strengthening in all directions
  - Balance exercises—see below
  - Calf raises (knee extended/knee bent)
  - Towel pick-ups
  - Heel/Toe walks

Sensorimotor Exercises

- Will start with weight shifting and progress to single leg balance.
  Single leg balance on wobble boards, Dyna Discs, trampoline, incline surfaces, Biomechanical Ankle Platform System (BAPS).

Open and Closed Kinetic Chain Exercises

- Manual resistance exercises in all ankle planes added
- Hip strengthening with Thera-Band and weight-bearing exercises can be done at this time.

Functional Exercises

- Continued gait training if needed at this point

Milestones for Progression to the Next Phase

- Absence of pain and evidence of union of the fracture on radiographs

Phase III (weeks 6 to 10)

Clinical Pearls

- Consider a firm last athletic shoe to minimize the stress at the fracture site.
- The screw head may be prominent and may become symptomatic in some patients when they return to normal shoe wear. Consider using a cut out pad to alleviate pressure at the styloid.

Goals

- Progression in activities as symptoms dictate
- Once asymptomatic and with evidence of fracture healing, patients can progress to running and jumping.
- Strengthening of the foot and ankle muscles is initiated and progression is carried out until discharge.
- Continued ankle and subtalar joint motion
- Continued cardiovascular fitness

Management of Pain and Swelling

- Pain should be minimal. Ice if needed.
- Continued ice can be used to help reduce the swelling if any is present with the increase in activity.

Techniques for Progressive Increase in Range of Motion

- Full range of motion should be achieved at this point
- Ankle range of motion exercises in all planes can be continued (dorsiflexion, plantar flexion, inversion and eversion)
  - Wall stretch, towel stretch, self-stretches with wobble boards or hand
- Plantar fascia stretching can be continued
  - Rolling with a can or bottle

Other Therapeutic Exercises

- Again, maintaining whole body cardiovascular fitness is a main goal.
- Core stability exercises and upper extremity strengthening can be continued.
  - Stability ball, planks, bridges, superman exercises

Activation of Primary Muscles Involved in Injury Area or Surgical Structures

- Peroneals, gastrocnemius, soleus, tibialis anterior/posterior, toe extensors/flexors
  - Thera-Band ankle strengthening in all directions
  - Balance exercises—see below
  - Calf raises (knee extended/knee bent)
  - Towel pick-ups
  - Heel/Toe walks

Sensorimotor Exercises

- Continued single leg balance on wobble boards, Dyna Discs, trampoline, incline surfaces, BAPS
- Progressing to Thera-Band resistance bands, ball toss, and perturbations.

Open and Closed Kinetic Chain Exercises

- Thera-Band ankle strengthening in all directions (Figure 44-14), toe flexor/extensor exercises (towel pick-ups), heal raises/soleus raises (Figure 44-15), squats/lunges, hip strengthening with Thera-Band

FIGURE 44-14. Therband strengthening of the ankle invertors.

Neuromuscular Dynamic Stability Exercises

- Dynamic reaction drills on the trampoline and progression into ball toss and perturbations on balance boards
- Standing single balance movement drills (Figure 44-16)
- Slide board or Pro Fitter

Plyometrics

- Starting with double leg and progressing to single leg (Figure 44-17)
- Platform jumps, progressing height depending on difficulty

Functional Exercises

- Jogging to running with progression from straight forward to side to side and cutting agility drills

Sport-Specific Exercises

- Depending on the sport, cutting, twisting, pivoting, and other sport related drills

FIGURE 44-15. Soleus raises using leg extension machine.

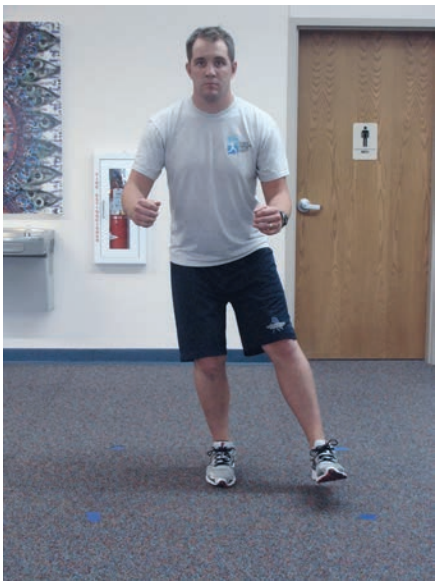

FIGURE 44-16. Standing single-leg balance dot drill.

Milestones for Progression to the Next Phase

- The rehab program needs to be individualized and adjusted for each athlete depending on the sport and the initial fracture site.
- Absence of pain on pain scale (0 to 10), full ankle range of motion per procedures of Norkin and White, restoration of strength in the foot and ankle measured by manual muscle testing per procedures of Daniels and Worthingham
  - Strength MMT 5/5 for peroneals, gastrocnemius, soleus, tibialis anterior/posterior, toe extensors/flexors
  - ROM
    - Dorsiflexion—20°
    - Plantarflexion—50°
    - First MTP flexion—30 to 45°
    - First MTP extension—50 to 70°
- Evidence of union of the fracture on follow-up radiographs

Criteria for Return to Sport

- Absence of pain, full ankle range of motion, restoration of strength in the foot and ankle
- Evidence of union of the fracture on follow-up radiographs

After Return to Sport

Continuing Fitness or Rehabilitation Exercises

- Total body fitness and overall cardiovascular fitness is very important and should be continued following this injury.

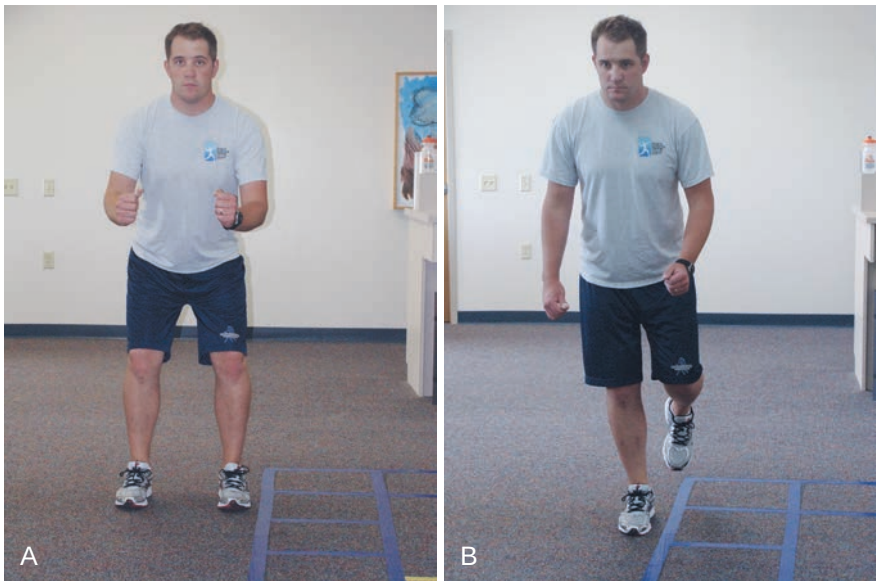

FIGURE 44-17. Progression of double leg jumping over line to single leg hoping.

- Maintaining foot and ankle strength/ROM, balance, and proprioception

Exercises and Other Techniques for Prevention of Recurrent Injury

- Mechanism of jumping and running to prevent reinjury
- Proper shoe wear, possible use of orthotics or external support during competition

Evidence

Aaron RK, Ciombor DM, Simon BJ: Treatment of nonunions with electric and electromagnetic fields. *Clin Orthop Relat Res* (419):21–29, 2004.

This is a review article in which the authors concluded that electric and electromagnetic fields had improved results in delayed and nonunion fractures compared with placebo treatment. (Level 4 evidence)

Clapper MF, O'Brien TJ, Lyons PM: Fractures of the fifth metatarsal. Analysis of a fracture registry. *Clin Orthop Relat Res* 238–241, 1995.

In this article a fracture registry was established. The authors found that avulsion fractures healed with immobilization, usually in 4 weeks; shaft/neck fractures healed in casts with WBAT in 4 to 6weeks; and Jones' fractures required a prolonged time to heal, on average 21.2 weeks. (Level 4 evidence)

Hislop H, Montgomery J: *Daniels and Worthingham's muscle testing: Techniques of manual examination*, ed 7, Philadelphia, 2002, Saunders.

This is a handbook on the manual evaluation of muscle strength testing. It provides instructions and guidance on patient positioning, muscle anatomy, grading, and assessment of every muscle. (Level 5 evidence)

Holmes GB, Jr: Treatment of delayed unions and non-unions of the proximal fifth metatarsal with pulsed electromagnetic fields. *Foot Ankle Int* 15:552–556, 1994.

This study looked at nine delayed unions and nonunions of the proximal fifth metatarsal that were treated with pulsed electromagnetic fields and found that the mean time of fracture healing was 3 months compared to 4 months without the pulsed electromagnetic fields. (Level 4 evidence)

Mindrebo N, Shelbourne KD, Van Meter CD, et al: Outpatient percutaneous screw fixation of the acute Jones fracture. *Am J Sports Med* 21:720–723, 1993.

This study used 9 varsity athletes, seven Division 1 scholarship athletes who sustained a Jones fracture that were treated with percutaneous screw fixation. The authors found an average return time to full competition was 8.5 weeks. (Level 4 evidence)

Mologne TS, Lundeen JM, Clapper MF, et al: Early screw fixation versus casting in the treatment of acute Jones fracture. *Am J Sports Med* 3:970–975, 2005.

In this randomized controlled trial, eighteen patients were randomized to cast treatment and nineteen patients were randomized to screw fixation. The authors found that early screw fixation results in faster times to union and return to sport compared with cast treatment. (Level 1 evidence)

Norkin C, White DJ: *Measurement of joint motion: A guide to goniometry*, ed 3, Philadelphia, 2003, F.A. Davis Company.

This is a handbook that describes in detail the standard way to perform goniometry. Every procedure is described in detail with documented norms of each joint. (Level 5 evidence)

Porter DA, Duncan M, Meyer SJ: Fifth metatarsal Jones fracture fixation with a 4.5-mm cannulated stainless steel screw in the competitive and recreational athlete: A clinical and radiographic evaluation. *Am J Sports Med* 33:726–733, 2005.

This is a case series where 23 consecutive athletes (24 feet) who were treated surgically were followed. The authors showed that a 4.5-mm cannulated screw could provide reliable and effective healing. The authors also demonstrated a functional progression program and postoperative rehabilitation program for the competitive and recreational athlete. (Level 4 evidence)

Multiple-Choice Questions

QUESTION 1. At what time frame is the athlete allowed to start running and jumping?

A. Week 2
B. Week 6
C. Week 12
D. Week 20

QUESTION 2. What is one of the main criteria that allow an athlete to start the running and jumping progression?

A. Normal mechanics of jumping
B. Full ROM
C. Full ankle and foot strength
D. Evidence of union of the fracture on follow up radiographs

QUESTION 3. Which tendon is sometimes irritated following the surgical approach so strengthening is sometimes delayed?

A. Peroneus brevis
B. Anterior tibialis
C. Posterior tibialis
D. Peroneus longus

QUESTION 4. Following the surgical fixation of a fifth metatarsal fracture, the patient is placed in?

A. CAM walker boot
B. Firm last shoe
C. Short leg cast
D. Normal foot wear

QUESTION 5. Indications for surgical treatment of fifth metatarsal fractures include?

A. Refractures
B. Symptomatic delayed union or non-union Jones Fracture
C. Acute Jones Fractures in athletes
D. All of the above

Answer Key

QUESTION 1. Correct answer: **B** (see Phase III Goals and Figure 44-17)

QUESTION 2. Correct answer: **D** (see Phase II Milestones for Progression to the Next Phase)

QUESTION 3. Correct answer: **A** (see Phase II Clinical Pearl)

QUESTION 4. Correct answer: **A** (see Brief Summary of Surgical Treatment)

QUESTION 5. Correct answer: **D** (see Indications for Surgical Treatment)

BEYOND BASIC REHABILITATION: RETURN TO FOOTBALL AFTER OPEN REDUCTION AND INTERNAL FIXATION OF JONES FRACTURE

Brad McMahon, MPT, and Timothy S. Mologne, MD

Introduction

ASPECTS OF FOOTBALL THAT REQUIRE SPECIAL ATTENTION IN REHABILITATION

- Football requires the athlete to run, plant, and cut effectively to perform at his or her highest level.
- Jones fractures are often caused by force overload as the athlete attempts to push off from the forefoot, but can also result from repetitive stress to the same area

- Historically Jones fractures have been challenging to get to heal with conservative treatment, with some patients not healing the fracture for 21.2 weeks.[1]
- These fractures have a high rate of nonunion and re-fracture despite prolonged treatment.[2]
- Conservatively managed patients are held out of running and jumping sports until there is fracture union.
- Surgical intervention is offered to patients to avoid prolonged immobilization and limited weight bearing, lessen the length of time away from the desired sport, and prevent future reinjury to the fifth metatarsal during sports participation.

Literature

- Jones fractures are well managed with intramedullary screw fixation with a shortened time to clinical and radiographic union as compared with cast treatment. The surgery group had median times to union and return to sport of 7.5 to 8 weeks.[2]
- Athletes returned to running by 5.5 weeks, full practice by 7.5 weeks, and full competition by 8.5 weeks on average.[3]
- In Collins case study the player began light football drills 21 days post surgery, full practice at the start of the fifth week, and back to competition by the end of the sixth week.[4]

Phase III: Sport-Specific Training

Program Design/Performance Training Program

Sport-Specific Concepts of Integrated Training

- To start with sport-specific training the patient should be pain free, have full ROM per procedures of Norkin and White, restoration of strength in the foot and ankle measured by manual muscle testing per procedures of Daniels and Worthingham, and have evidence of union of fracture on radiographs.
  - Strength MMT 5/5 for peroneals, gastrocnemius, soleus, tibialis anterior/posterior, toe extensors/flexors
    - Thera-Band ankle strengthening in all directions
    - Balance exercises (see the following)
    - Calf raises (knee extended/knee bent)
    - Towel pick-ups
    - Heel/toe walks
  - ROM
    - Dorsiflexion: 20°
    - Plantarflexion: 50°
    - First MTP flexion: 30° to 45°
    - First MTP extension: 50° to 70°

FIGURE 44-18. Single leg balance with body blade.

- Concepts that are included in the training for a football player are multiplanar running, cutting, strength, power, speed, agility, and contact drills.
  - Flexibility joint mobility
    - Maintain ankle and subtalar motion. (Calf stretching against wall, towel stretch, and self-stretching for inversion/eversion.)
- Sensorimotor and balance training
  - Single-leg balance on wobble boards, Dyna Disc, trampoline, and inclined surfaces.
  - Progressing to Thera-Band resistance bands, ball toss, and perturbations (Figure 44-18).
  - Biomechanical ankle platform system (BAPS) and dynamic reaction drills on the wobble board, Dyna Disc, and trampoline.
  - Slide board (Figure 44-19) or Pro-fitter
- Core training
  - Stability ball, planks, bridges, superman exercises (Figure 44-20).

TIMELINE 44-3: **Return to Football After Open Reduction and Internal Fixation of Jones Fracture**

PHASE I (weeks 0 to 2)	PHASE II (weeks 2 to 6)	PHASE III (weeks 6 to 10)

• Protected weight bearing with CAM walker boot and crutches
• Early and gentle ankle ROM
• Ice and pain meds as needed
• Maintain cardiovascular fitness (stationary bicycle)
	• Full weight bearing in firm last or hard-soled shoe
	• Continued ankle ROM and plantar fascia stretching
	• Ice as needed for swelling
	• Start single leg balance exercises
	• Manual resistance exercises in all ankle planes
		• Foot orthotic still may be used with an external support
		• Full ankle ROM
		• Strengthening of foot and ankle with resistance bands
		• Single leg balance and proprioception exercises progressed
		• Dynamic reaction drills
		• Jumping and plyometrics added
		• Running and sport-specific drills
		  • Cone/ladder drills
		  • Cutting/twisting drills
		  • Figure-eight/zig-zag running
		  • Backpedaling
		  • Shuttle runs/40-yard dash
		• Depending on the position played
		  • Route running
		  • Blocking and tackling drills
		  • Noncontact/contact drills

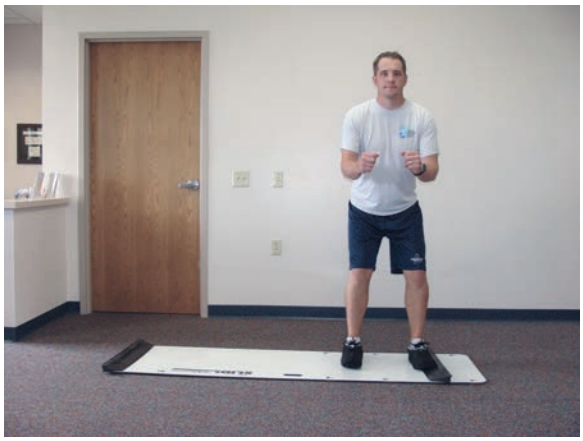

FIGURE 44-19. Rehabilitation on slide board.

FIGURE 44-20. Core strengthening side plank exercise.

- Cardio respiratory training
  - Should be maintained initially with cycling, pool workouts, or stair stepping until progression into running is approved.
- Training for speed, agility, and quickness (SAQ)
  - Jogging to running with progression from straight forward to side-to-side and cutting agility drills
  - Cone/ladder drills
  - Cutting/twisting drills
  - Figure-eight/zig-zag running
  - Backpedaling
  - Shuttle runs/40-yard dash
- Plyometric training
  - Starting with double leg and progressing to single leg (Figure 44-21)
  - Platform jumps, progressing height depending on difficulty
- Sport-specific training
  - Depending on the position played: route running, blocking, and tackling drills. All drills being progressed from noncontact to contact.

Olympic Lifts Used in the Training Program

Training Principles Used in the Design of the Program

- The principles of progression, overload, variation, and individuation are all used. Treatment should be individualized and based on the patient's needs.
- Intensity and the duration of the activities and programs are increased over time and as the patient can tolerate.
- Monitoring of patient pain and swelling of the foot must be done closely.

Sports Performance Testing

General Information

- General history
- Medical history, including medical ailments, genetic conditions that might affect strength, ligamentous laxity, and proprioception

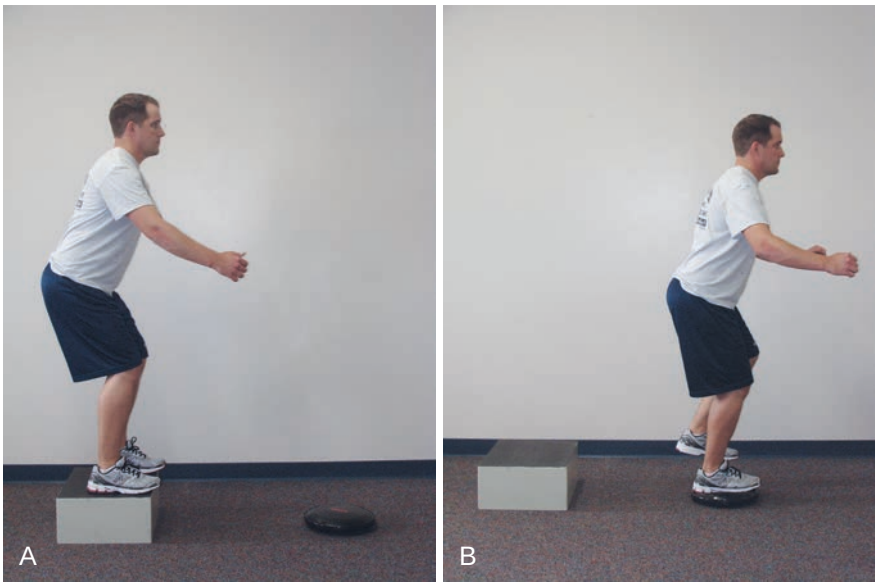

FIGURE 44-21. Single leg Plyometric jump onto Dyna Disc starting position (**A**) and landing position (**B**).

- Sports injury history, including the specifics of the current foot injury and prior injuries
- Surgical history, occurrence of any postoperative complications, including motion loss, infection, neurological injury, and thromboembolic events

Specific Objective Tests

- ROM measurements of foot and ankle
- Dorsiflexion: 20°
- Plantarflexion: 50°
- First MTP flexion: 30° to 45°
- First MTP extension: 50° to 70°
- Manual muscle testing of foot and ankle
  - Strength MMT 5/5 for peroneals, gastrocnemius, soleus, tibialis anterior/posterior, toe extensors/flexors
    - Thera-Band ankle strengthening in all directions
    - Balance exercises (see the following)
    - Calf raises (knee extended/knee bent)
    - Towel pick-ups
    - Heel/toe walks
- Single leg balance assessment (with perturbations) in comparison to nonoperative side hop and jumping tests
  - Single leg hop and standing vertical in comparison to nonoperative side
- Analysis of gait cycle and biomechanics
- Orthopaedic Foot Ankle Society Mid Foot Score

Specific Criteria for Release to Unsupervised Complete Participation in Football

- Pain-free, full ROM, and strength of the foot and ankle, and have evidence of union of fracture on radiographs.
- A pain-free functional progression program of running 3 to 4 days a week, 30 minutes at a time.[5]

Recommended Ongoing Exercises

- Football requires a lot of fast movements, running, cutting, and contact. Total body fitness and overall cardiovascular fitness is very important and should be continued following this injury.
- Maintaining foot and ankle strength/ROM, balance, and proprioception
- Proper shoe wear, possible use of custom orthotics or external support during competition

Evidence

Clapper MF, O'Brien TJ, Lyons PM: Fractures of the fifth metatarsal. Analysis of a fracture registry. *Clin Orthop Relat Res* 238–241, 1995.

A fracture registry was established in this article. The authors found that avulsion fractures usually healed with immobilization in 4 weeks, shaft/neck fractures healed in casts with WBAT in 4 to 6 weeks, and Jones' fractures required a prolonged time to heal, on average 21.2 weeks. (Level IV evidence)

Collins KS, Streitz W: Bilateral Jones fractures in a high school football player. *J Athl Train* 31:253–256, 1996.

This is a case report that presented a high school football player with bilateral Jones fractures who was treated both conservatively and with a screw fixation. It is specific to football and shows the progression of both surgical and nonsurgical treatments. (Level IV evidence)

Hislop H, Montgomery J: *Daniels and Worthingham's muscle testing: Techniques of manual examination*, ed 7, 2002, Saunders.

This is a handbook on the manual evaluation of muscle strength testing. It provides instructions and guidance on patient positioning, muscle anatomy, grading, and assessment of every muscle. (Level V evidence)

Low K, Noblin JD, Browne JE, et al: Jones fractures in the elite football player. *J Surg Orthop Adv* 13:156–160, 2004.

This study characterized Jones fracture treatments in the National Football League between 1988 and 2002. There were 86 Jones fractures identified, with 46 treated surgically. A questionnaire was also sent out to all team physicians, and the consensus was that surgical treatment is recommended 77% of the time over nonsurgical treatment and is the treatment of choice for most physicians. (Level IV evidence)

Magalaya CL, Cook C, Zarzour H, et al: Return to division IA football following a 1st metatarsophalangeal joint dorsal dislocation. *Am J Sports Phys Ther* 5:131–142, 2010.

This is a case report that focuses on returning an athlete to football following a metatarsophalangeal joint dorsal dislocation. It is very specific to football and shows a rehabilitation program for a collegiate football player returning from a foot/ankle injury. (Level IV evidence)

Mindrebo N, Shelbourne KD, Van Meter CD, et al: Outpatient percutaneous screw fixation of the acute Jones fracture. *Am J Sports Med* 21:720–723, 1993.

This study used nine varsity athletes and seven Division 1 scholarship athletes who sustained a Jones fracture and who were treated with percutaneous screw fixation. The authors found an average return time to full competition of 8.5 weeks. (Level IV evidence)

Mologne TS, Lundeen JM, Clapper MF, et al: Early screw fixation versus casting in the treatment of acute Jones fracture. *Am J Sports Med* 33:970–975, 2005.

In this randomized controlled trial, 18 patients were randomized to cast treatment and 19 were randomized to screw fixation. The authors found that early screw fixation results in faster times to union and return to sport compared with cast treatment. (Level I evidence)

Norkin C, White DJ: *Measurement of joint motion: A guide to goniometry*, ed 3, Philadelphia, 2003, F.A. Davis.

This is a handbook that describes in detail the standard way to perform goniometry. Every procedure is described in detail with documented norms of each joint. (Level V evidence)

Porter DA, Duncan M, Meyer SJ: Fifth metatarsal Jones fracture fixation with a 4.5-mm cannulated stainless steel screw in the competitive and recreational athlete: A clinical and radiographic evaluation. *Am J Sports Med* 33:726–733, 2005.

This is a case series in which 23 consecutive athletes (24 feet) who were treated surgically were followed. The authors

showed that a 4.5-mm cannulated screw could provide reliable and effective healing. The authors also demonstrated a functional progression program and postoperative rehabilitation program for the competitive and recreational athlete. (Level IV evidence)

Multiple Choice Questions

QUESTION 1. On average an athlete who sustains a Jones fracture and elects to have surgery by screw fixation can expect to return to competition at

A. 2 to 3 weeks.
B. 12 to 14 weeks.
C. 7 to 9 weeks.
D. 4 to 5 weeks.

QUESTION 2. To return to competition an athlete must have which of the following?

A. Full ROM of foot/ankle
B. Evidence of union of fracture upon radiographs.
C. Pain-free running
D. All of the above

QUESTION 3. Intervention for a Jones Fracture is offered to patients to

A. avoid prolonged immobilization.
B. lessen the length of time away from the sport.
C. prevent future reinjury of the fifth metatarsal.
D. All of the above

QUESTION 4. Jones fractures sometimes are a challenge to heal with conservative treatment. According to the literature some can take as long as _____ weeks to heal.

A. 21
B. 3
C. 30
D. 12

QUESTION 5. According to Norkin and White (*Measurement of Joint Motion: A Guide to Goniometry*), ankle dorsiflexion norms are

A. 10°.
B. 30°.
C. 20°.
D. 25°.

Answer Key

QUESTION 1. Correct answer: **C** (see Introduction: Literature)

QUESTION 2. Correct answer: **D** (see Specific Criteria for Release to Unsupervised Complete Participation in Football)

QUESTION 3. Correct answer: **A** (see Introduction)

QUESTION 4. Correct answer: **A** (see Introduction)

QUESTION 5. Correct answer: **D** (see Phase III)

Chapter 45

First Metatarsophalangeal Joint Sprain (Turf Toe)

INTRODUCTION

Stephen Gould, MD, MPH, and Kenneth J. Mroczek, MD

Epidemiology

- The term *turf toe* first appeared in literature in 1976 as reported by Bowers and Martin to describe plantar capsuloligamentous sprain of the first metatarsophalangeal (MTP) joint related to hard artificial surfaces and insubstantial footwear.[1]

Age and Sex

- There are no age or sex predilections for this injury.
- Mechanism of injury, playing surface, and individual biomechanics are predisposing factors to the injury.[2]

Sport and Position

- Football players (running backs, wide receivers, defensive backs, offensive linemen, tight ends) have a higher incidence of turf toe injury[3] but the injury is also seen in other sports/activities such as soccer and dance.
- Forty-five percent of professional football players surveyed reported suffering from turf toe.[3]
- Turf toe can cause significant functional disability.
- Coker et al. reported a series of injuries in University of Arkansas football players. The authors described the severity of turf toe injury in terms of lost playing time and delayed return to play, even when compared with more common, but debilitating injuries.[4]
- Hallux metatarsophalangeal joint sprains occur in other sporting activities such as dance (modern and classical) and beach volleyball. "Sand Toe" is the term used to describe this injury in beach volleyball.[5]

Pathophysiology

Intrinsic Factors

- Major contributors
  - Increased ankle dorsiflexion[2]
    - Mean ankle dorsiflexion of the uninjured side in injured players was 13.33° compared with 7.87° in uninjured players.[3]
  - Flattening of the first MTP[2]
  - Foot pronation[2]
- Minor contributors
  - Decreased first metatarsophalangeal dorsiflexion is associated with turf toe injury (40.6 ± 15.1° in football players with turf toe versus 48.4 ± 12.8° in football players without history of turf toe)[6]
  - Hallux degenerative joint disease[2]
  - Prior first MTP joint injury
  - Pes planus
  - Athlete's weight[2]
  - Number of years in professional football
    - 5.2 years for injured versus 3.0 for controls[3]

Extrinsic Factors

- Playing surface
  - Artificial turf and playing surfaces.[2] The introduction of these manufactured surfaces in the mid-1960s resulted in a loss of shock-absorbing characteristics compared with grass turf.
  - Eighty-three percent of patients report initial injury on an artificial surface.[3]
- Footwear
  - The forces the halluces experience are compounded by the friction between athletic shoe and turf.[2]

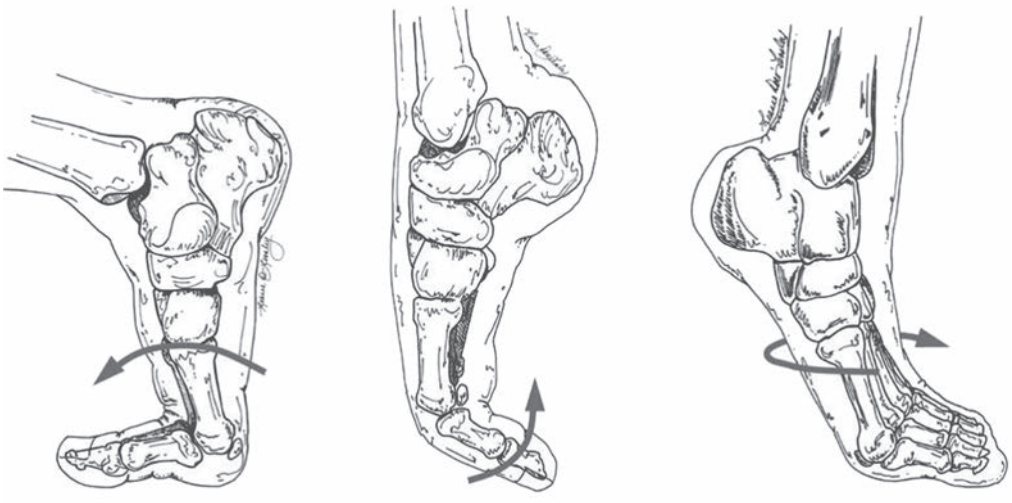

FIGURE 45-1. Loading mechanisms that can result in turf toe injury.

- Lighter, more flexible shoes with increased toe box flexibility and decreased number of cleats in the shoe[2] provide greater agility but offer less protection to the halluces from impact.

Traumatic Factors

- The most common mechanism of injury, accounting for 85% of injuries, results from forced hyperdorsiflexion at the first MTP.[3] This occurs when the forefoot is planted and the heel rises from the ground. If this stress causes the hallux to dorsiflex beyond its biomechanical limits, damage to the capsule at the neck of the first MTP will occur.[2] This is because the joint capsule attachment is weaker at this site than at the proximal phalanx.[3]
- The biomechanics of this injury results from distal traction on the medial and lateral sesamoids during forced hyperextension. This transfers the mechanical load to the dorsal aspect of the metatarsal head. This stress can cause partial or complete disruption of the plantar plate. Injury to the plantar plate results in impaction of the articular surfaces of the proximal phalanx to the metatarsal head during extension of the MTP. This is the most severe form of injury to the soft tissues of the first MTP.[5]
- Eighty-five percent of turf toe injuries result from hyperextension of the first metatarsophalangeal joint.[3] Less common mechanisms of injury include plantar flexion injury to the first MTP joint, and varus or valgus stress injuries.[7] Hyperplantarflexion injuries are more commonly seen in dance and beach volleyball (Figure 45-1).[5]
- Various football positions are susceptible to this injury.
  - Offensive linemen when pushing off from a stance, can hyperextend the first MTP.
  - Running backs and receivers may be also be injured if tackled from behind, with their forefoot planted on the ground, if another player falls onto their leg causing hyperextension at the first MTP (Figure 45-2).
  - Essentially, any activity that results in forced hyperdorsiflexion on the great toe can result in damage to the first MTP. Additional examples include forced dorsiflexion due to tackling or due to impact of the first MTP against the toe box of the shoe during rapid deceleration.

Classic Pathological Findings

- While initially used to describe only a sprain or strain of the soft tissue support structures of the first MTP, the term turf toe has come to designate a spectrum of injuries from sprains to frank dorsal dislocation of the toe.[8]
- Clanton et al developed a classification system to describe the severity of turf toe injuries. This system remains utilized today to help dictate treatment and return to play.[9]

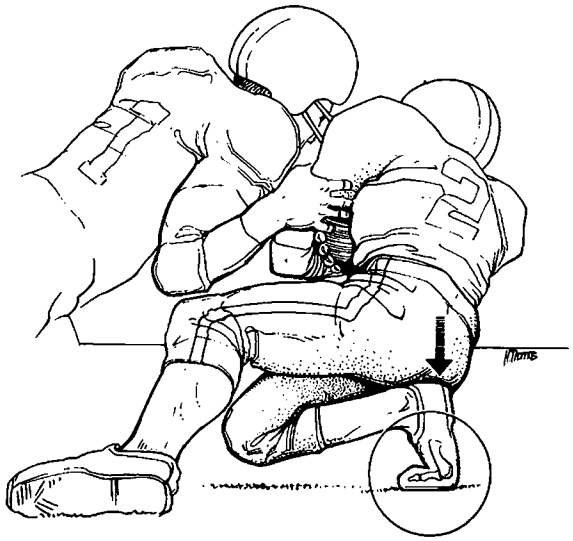

FIGURE 45-2. Forced dorsiflexionflexion injury in football. *(Redrawn from Rodeo SA, O'Brien S, Warren RF, Barnes R, Wickiewicz TL, Dillingham MF: Turf-toe: An analysis of metatarsophalangeal joint sprains in professional football players. Am J Sports Med 18(3):280–285, 1990.)*

- Grade I injuries: least severe; strain of the capsuloligamentous complex without loss of its functional integrity.[7,10,11]
- Grade II injuries are more severe and represent partial thickness tearing of the plantar plate and capsular structures.[7,10,11]
- Grade III injuries are the most severe. This grade of injury may be used to describe either chronic effects of a disrupted capsule,[7] or to describe an acute injury with complete disruption of the capsuloligamentous complex. With this grade of injury, the plantar plate may be completely avulsed from the metatarsal neck, resulting in impaction of the metatarsal head during full extension of the joint.[3,7,10,11]

Clinical Presentation

History

- Typical presentation includes great toe pain in an athlete whose sport exposes him or her to hyperextension of the toe on a hard surface. Football players, soccer players, and dancers, among others may suffer from this injury.
- The patient may complain of pain, swelling, and tenderness of the plantar aspect of the MTP, as well as inability to push off with the great toe.[7]

Physical Examination

Key Elements of Exam

- Observe for general deformity of the toe, presence of swelling and ecchymosis (ecchymosis indicates fracture or disruption of tendon/ligament).[11]
- Palpate joint structures including dorsal metatarsal head and neck, dorsal aspect of the proximal phalanx, and the sesamoids to assess integrity and presence of tenderness to palpation.[11]
- Stress tests
  - Abduction stress test: assesses medial collateral ligament, medial capsule, abductor halluces[11]
  - Adduction stress test: assesses lateral collateral ligament, lateral capsule, and adductor halluces[11]
  - Lachman-type maneuver to assess plantar plate[10,11]
  - Flexor hallucis brevis strength and integrity assessment[11]

Abnormal Findings

- Grade I: Plantar or medial tenderness to palpation; minimal to no swelling; minimal or no ecchymosis[7,8,10]
- Grade II: Diffuse tenderness to palpation; moderate swelling and ecchymosis; painful and restricted range of motion. Symptoms may progress and athletes can lose up to 2 weeks of play.[7,8,10]
- Grade III: Severe tenderness to palpation; marked swelling and ecchymosis, and restricted range of motion. The patient usually will avoid weight bearing due to pain. Athletes can miss up to 6 weeks or more of play. Hallux plantarflexion weakness or frank instability of hallux MTP can occur.[7,8,10,11]

Pertinent Normal Findings

- Grade 1: no visible bruising. There is little change in the range of motion and the patient can continue to bear weight.[7]

Imaging

Grade I

- Radiographs are normal. An MRI may demonstrate mild soft tissue edema surrounding the capsule; however, all components of the capsule remain intact.[7,10]

Grade II

- Radiographs are typically normal. An MRI will show adjacent soft tissue edema. Partial thickness disruption may be seen as fluid signal intensity extending partially through the plantar plate and capsular structures. The sesamoid bones typically remain in normal position.[7,10]

Grade III

- Radiographs are abnormal and may demonstrate an associated capsular avulsion, compression fracture; sesamoid fracture, diastasis, or proximal migration. Comparison films with the contralateral foot or preinjury radiographs may be helpful in detecting sesamoid abnormalities.[7,10,11]
- A small fleck of bone might be found avulsed from the proximal phalanx or the sesamoid, suggesting a capsular disruption.[8]
- An MRI will also demonstrate these findings and can also reveal the extent of injury to each component of the capsuloligamentous structure (Figure 45-3), including the plantar plate, collateral ligaments, as well as the flexor and extensor tendons.[7,10,11]
- An MRI can also assess the integrity of the articular surface of the MTP joint.[7]

General Imaging

- Comparison radiographs of the contralateral foot are mandatory as patients with a rupture of the plantar plate will have proximal migration of one or both sesamoids.[8]
- Forced dorsiflexion lateral radiographs should be obtained if there is clinical suspicion for a plantar plate disruption. If there is a complete disruption of the MTP joint complex, the sesamoids will not track distally with the hallux extension and will appear to be located proximally.[8]
- An MRI is useful for both soft-tissue injury and osseous damage. T2-weighted images will identify subtle injuries. An MRI is recommended for all grade II or III injures to help guide the treatment plan and return to play.[8]

Differential Diagnosis

- Gout: differentiated by associated erythema and warmth of joint; no ecchymosis present; severe pain and restriction of motion

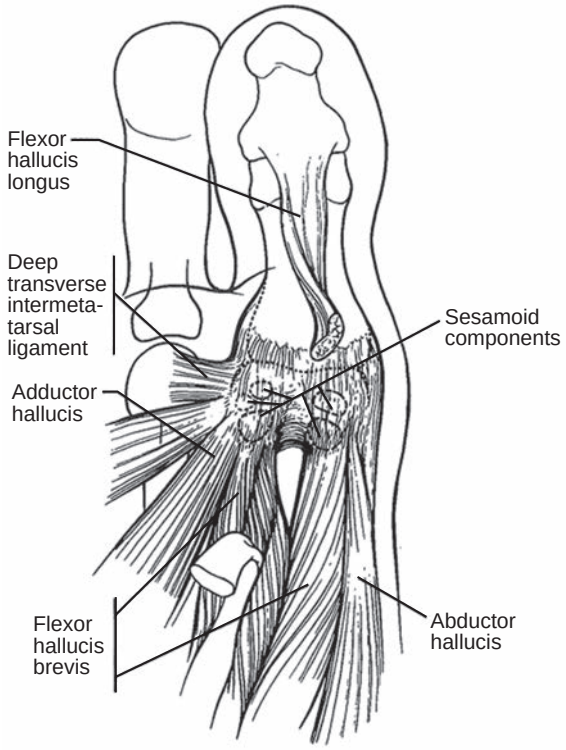

FIGURE 45-3. Anatomy of the capsuloligamentous structures. *(Redrawn from Rodeo SA, O'Brien S, Warren RF, Barnes R, Wickiewicz TL, Dillingham MF: Turf-toe: An analysis of metatarsophalangeal joint sprains in professional football players. Am J Sports Med 18(3):280–285, 1990.)*

- First metatarsal stress fracture: differentiated by lack of erythema/ecchymosis; point tenderness and indolent course
- Soft tissue mass (bursitis, granuloma, Morton neuroma): differentiated by minimal pain with palpation; lack of skin findings

Treatment

Nonoperative Management

- Immobilization, cryotherapy, NSAIDS
- Nonsurgical treatment options involve limiting the range of motion of the first MTP
  - Taping of the toe[7,10,11]
  - Orthotics or "turf toe plate" in the shoe[7,11]
  - Rocker sole shoe[10]
- Walking boot and crutches as needed[8,11]
- Long-term immobilization in boot or cast[8,11]
- Steroid injection is controversial; some authors believe it may predispose to further soft tissue damage.[11]

Guidelines for Choosing Among Nonoperative Treatments

- Grade I: The prognosis for full recovery is good and the patient can usually continue to play with only mild discomfort.[3,7,12] Grade I injuries may be treated with taping of the toe and the use of a stiff insole in the shoe.[7] Grade II: Treatment of grade II injuries is usually conservative with pain control, elevation, rest, and icing of the joint. Motion of the joint may be permitted in several days as symptoms permit.[7] Walking boot and crutches as needed; may need taping on return to play.[8]
- Grade III: The athlete will lose a minimum of 4 to 6 weeks of playing time, and treatment may require prolonged immobilization or surgery.[7]

Surgical Indications

Relative

- Large capsular avulsion with unstable joint
- Diastasis of bipartite sesamoid
- Diastasis of sesamoid fracture
- Retraction of sesamoid(s)
- Traumatic hallux valgus deformity
- Vertical instability (positive Lachman test)
- Loose body
- Chondral injury
- Failed conservative treatment[8,11]

Absolute

- Irreducible joint dislocation

Aspects of History, Demographics, or Exam Findings that Affect Choice of Treatment

- Grade I injury, or sprain of the capsuloligamentous structures, allows athletes to return to competition as tolerated. Taping in slight plantarflexion to diminish motion at the first MTP may alleviate symptoms. In addition, athletes can use orthotics or turf toe plates to minimize hallux MTP extension.[8]
- Grade II injuries, or partial plantar capsular ligamentous rupture, will generally result in loss of playing time of at least 2 weeks. These injuries are treated with a similar regimen of relative immobilization of the first MTP, similar to that used for grade I injuries.[7] Some authors further advocate a 2-week period of non–weight-bearing.[11]
- Grade III injury, or complete plantar capsular ligamentous rupture, can have a prolonged recovery time. With these injuries, a 4- to 8-week period of immobilization followed by rehabilitation is appropriate before return to play.[8,11]

Aspects of Clinical Decision Making When Surgery Is Indicated

- Conservative treatment with immobilization, cryotherapy, and NSAIDS is usually successful, so operative management is rarely considered in acute injury.
- However, operative intervention is required in the acute setting in the case of irreducible joint dislocation.
- If conservative measures fail, surgical intervention should be considered. This is especially true if the patients suffer loss of performance, such as loss of push-off strength.[8]
- Because of the infrequency with which these injuries are surgically repaired, some authors recommend that they should be referred to a foot and ankle specialist.[8]
- Consideration should be given to surgical repair of the ruptured capsuloligamentous complex (Grade III) in collegiate and professional athletes, particularly football players.[13]

Evidence

Bowers KD, Jr, Martin RB: Turf-toe: A shoe-surface related football injury. *Med Sci Sports* 8(2):81–83, 1976.

This paper is the first to describe turf toe injuries, or plantar capsule-ligament sprains of the great toe metatarsophalangeal joint. Predisposing factors were noted to be playing surface hardness and shoe stiffness. (Level V evidence)

Brophy RH, Gamradt SC, Ellis SJ, et al: Effect of turf toe on foot contact pressures in professional American football players. *Foot Ankle Int* 30(5):405–409, 2009.

In an assessment of 44 players on one National Football League team, this study showed that turf toe injury is associated with decreased MTP motion, 40.6 ± 15.1° in football players with turf toe versus 48.4 ± 12.8° in football players without history of turf toe. (Level IV evidence)

Coker TP, Arnold JA, Weber DL: Traumatic lesions of the metatarsophalangeal joint of the great toe in athletes. *Am J Sports Med* 6(6):326–334, 1978.

In a case series of injuries in University of Arkansas football players over three seasons, turf toe injuries caused more lost playing time and delayed return to play when compared to ankle sprains. The authors noted an average of 6.0 turf toe injuries per season. (Level IV evidence)

Rodeo SA, O'Brien S, Warren RF, et al: Turf-toe: An analysis of metatarsophalangeal joint sprains in professional football players. *Am J Sports Med* 18(3):280–285, 1990.

A case series of eighty active professional football players with first metatarsophalangeal joint sprains found the primary mechanism of injury (85%) to be hyperextension. The majority of initial injuries (83%) occurred on artificial turf and decreased range of motion of the first metatarsophalangeal joint was a significant outcome after turf toe injury.) Level IV evidence)

Multiple-Choice Questions

QUESTION 1. What biomechanical factor predisposes an athlete to a turf toe injury?

A. Decreased ankle dorsiflexion
B. Increased ankle dorsiflexion
C. High arches
D. Prior anterior talofibular ligament injury

QUESTION 2. The most common mechanism of injury to the first metatarsal ligaments is

A. hyperplantarflexion.
B. hyperextension/hyperdorsiflexion.
C. varus stress.
D. valgus stress.

QUESTION 3. Which grade of injury represents partial thickness tearing of the plantar plate and capsular structures?

A. Grade 1
B. Grade 2
C. Grade 3
D. Grade 4

QUESTION 4. Which of the following is not an indication for surgical repair?

A. Vertical instability
B. Loose body
C. Partial tear of the capsuloligamentous complex
D. Chondral injury

QUESTION 5. If treated conservatively, Grade 3 injuries are usually treated with immobilization for what period of time?

A. 1 week
B. 2 weeks
C. 3 weeks
D. 4 or more weeks

Answer Key

QUESTION 1. Correct answer: **A** (see Pathophysiology, Major Contributors)

QUESTION 2. Correct answer: **B** (see Pathophysiology; Mechanism of Injury)

QUESTION 3. Correct answer: **B** (see Clinical Presentation)

QUESTION 4. Correct answer: **C** (see Treatment; Surgical Indications)

QUESTION 5. Correct answer: **D** (see Treatment)

NONOPERATIVE REHABILITATION OF FIRST METATARSOPHALANGEAL SPRAIN (TURF TOE)

Smita Rao, PT, PhD, and Kenneth J. Mroczek, MD

GUIDING PRINCIPLES OF NONOPERATIVE REHABILITATION

- Treatment of turf toe is based on the grade of injury (Grade I, II, or III).
- Excessive dorsiflexion at the first metatarsophalangeal joint must be prevented.
- Return to activity decisions are sport- and position-dependent.

Phase I (weeks 0 to 4): Early Protection

Note: The duration of this phase depends on the Grade of injury. Progression to Phase II is based on resolution of symptoms.

- For Grade I injuries, minimal immobilization and early progression to Phase II is recommended.
- For Grade II injuries, the Early Protection phase may be expected to last 2 weeks.
- Grade III injuries, immobilization may be part of nonsurgical as well as postoperative management.
- As part of the initial nonsurgical treatment, immobilization may last up to 4 weeks based on the severity of symptoms.
- After surgical reconstruction, the patient is non-weight bearing for 4 weeks. Although gentle range of motion can be initiated 5 to 7 days postoperatively, immobilization in a toe spica and joint protection is maintained the remainder of the time.

Goals

- The main goals of Phase I (early protection) are to reduce pain and swelling and facilitate the healing of injured tissue.

Protection

- For Grade I injuries, immobilization with taping and early progression to Phase II is recommended.
- Grade II injuries are treated with immobilization in the form of taping, or a short leg walking boot with crutches. A short leg walking cast may be used in lieu of the walking boot. A toe extension spica may be incorporated in the cast to prevent excessive dorsiflexion of the first metatarsophalangeal (MTP) joint. The patient is allowed to bear weight as tolerated.
- Grade III injuries usually require immobilization in plantar flexion to facilitate healing of ruptured plantar structures, consequently a short leg cast with toe spica or walking boot with crutches is used.

TIMELINE 45-1: **Nonoperative Rehabilitation of First Metatarsophalangeal Sprain (Turf Toe)**

PHASE I (weeks 0 to 4)	PHASE II (weeks 4 to 12)		PHASE III (weeks 12 to 16)
	(weeks 4 to 8)	(weeks 8 to 12)	
• Toe spica in 10° of plantarflexion, and walking boot (non–weight-bearing) • Elevation • PT modalities to address pain, swelling • Supervised passive motion initiated on day 5 to 7 • Transition to removable splint with walking boot	• Active first MTP motion • Partial weight bearing/ weight bearing as tolerated (WBAT) • Weight bearing may be deferred if osteochondral injury present • PT modalities to address pain, swelling, scar healing, and range of motion • Hydrotherapy if available • Therapeutic exercise (muscle strengthening, balance) • Taping	• DC walker, transition to rocker sole shoe or stiff-sole shoe • PT modalities as needed • PROM—full • Mobilizations as needed • Therapeutic exercise (muscle strengthening, balance, bicycling) • Graduated increase in intensity and duration of weight-bearing activity • Taping and/or Morton's extension	• PT modalities as needed • PROM—full • Mobilizations as needed • Taping and/or Morton's extension as needed • Return to activity, sport-specific training • Patient education: Full recovery may take from 24 to 52 weeks. • Injury surveillance and prevention (maintain conditioning and form)

Management of Pain and Swelling

- Although taping is recommended for Grade I and II injuries, it should be noted that taping is not used in the acute setting because of the risk of circulatory compromise.
- Rest, ice, compression, and elevation (RICE) are used in the acute stage to manage pain and swelling. Additional modalities such as cryotherapy (in the form of cold packs), contrast baths, pulsed ultrasound, and interferential electrical stimulation may be used if needed.[1]
- When swelling is well controlled and there is no risk of circulatory compromise, taping may be instituted.

Techniques for Progressive Increase in Range of Motion

- With the first MTP joint immobilized and protected from excessive dorsiflexion, the patient is encouraged to perform ankle circles and ankle pumps.

Other Therapeutic Exercises

- Strength training for the core, upper extremities, and the contralateral extremity should continue.
- Aerobic conditioning can be maintained using an upper extremity bicycle ergometer.
- Open chain exercises for the proximal muscles of the involved lower extremity are allowed (hamstring curls, leg extensions)

Activation of Primary Muscles Involved

- In this phase, activation of the flexor hallucis longus and extensor hallucis longus is minimized.
- To minimize loads at the forefoot and hallux, the patient is advised to limit activities involving strong push-off phase and strong contraction of the calf muscles.

Open and Closed Kinetic Chain Exercises

- CKC exercises are limited to the contralateral limb.
- Resisted OKC exercises of the proximal muscles (hamstrings, quadriceps, glutei) are recommended.
- Ankle circles and ankle pumps (OKC ankle exercises) are used to reduce swelling and maintain range of motion.

Sport-Specific Exercises

- Aerobic fitness should be maintained through cross-training.

Milestones for Progression to the Next Phase

- Resolution of symptoms (pain and swelling) is the chief criterion used to progress to the Phase II (activity progression)

Phase II (weeks 4 to 12): Activity Progression

Note: The duration of this phase depends on the grade of injury. Resolution of swelling and pain serve as criteria for progression from Phase I (early protection) to Phase II (activity progression).

- For Grade I injuries, Phase II rehabilitation may begin as soon as swelling is well controlled and the risk of circulatory compromise is ruled out.
- Grade II injuries may begin Phase II rehabilitation within 3 to 7 days following the initial injury.
- For Grade III injuries, Phase II rehabilitation may be initiated at 3 to 4 weeks following injury in the initial nonsurgical management. In the postsurgical management of turf toe reconstruction, Phase II rehabilitation may being on the fifth to seventh postoperative day.

Goals

- The chief goal of Phase II is to restore pain-free range of motion and ability to walk without pain.

Protection

- Taping provides minimal mechanical restraint.
- For Grade I and II injuries during Phase II rehabilitation, the use of rigid, stiff-soled, steel-shanked shoes is recommended to limit excessive first MTP dorsiflexion during weight-bearing activities.
- Alternatively patients may prefer to use an orthotic device like a carbon graphite shoe insert or Morton's extension (Figure 45-4). These devices may be full length (extends from the posterior heel to the tip of the great toe) or three-quarter length, available over the counter or through custom fabrication. They are intended to be rigid and limit the amount of the dorsiflexion experienced at the first MTP joint. They are available in varying grades of carbon graphite and

FIGURE 45-4. Over the counter orthotic devices. From right to left: full-length carbon graphite shoe insert (*contoured*); full-length carbon graphite shoe insert (*flat*), and three-quarter length Morton's extension (*flat*).

polypropylene. Thicker grades are stiffer. For patient comfort, a soft, viscoelastic insole can be used over the carbon graphite shoe insert or Morton's extension.
- For Grade III injuries, Phase II rehabilitation includes protection in a toe spica and walking cast or walking boot with crutches.
- If required a toe spacer or separator is used to maintain frontal plane alignment of the hallux and prevent hallux valgus.
- Gentle passive range of motion is instituted by the fifth to seventh postoperative day.
- Four weeks postoperatively, active range of motion and weight bearing as tolerated are initiated.
- Eight weeks postoperatively, the patient is allowed to transition to rigid shoes. In protective footwear, gradual activity progression is encouraged.

Management of Pain and Swelling

- As in Phase I, principles of RICE (rest, ice, compression, elevation) are used to achieve pain control and reduce swelling. Additional modalities may be added if required.

Techniques for Progressive Increase in Range of Motion

- Gentle passive plantarflexion to prevent adhesions and loss of sesamoid mobility is encouraged with the overall goal of maintaining joint motion required for gait while avoiding excessive dorsiflexion.
- Manual therapy in the form of joint mobilizations can be used for pain relief and to restore range of motion. Initially, distraction and/or Kaltenborn Grade I anteroposterior glides with oscillations are recommended. As the patient progresses and range of motion improves, Kaltenborn Grade II and III glides (Figure 45-5) and mobilizations with movement (MWM) are appropriate.
- Tender points or trigger points in the calf muscles may be treated with ischemic compression and soft tissue mobilization techniques.
- Non–weight-bearing stretches for the gastrocnemius and soleus muscles should be prescribed, with progression to weight-bearing stretches.

Other Therapeutic Exercises

- Based on sport and/or activity, other therapeutic exercises are continued to maintain lower limb and core strength and flexibility. These include gastrocnemius, hamstrings, rectus femoris, iliotibial band, and iliopsoas stretches.
- Open chain resisted exercises like hamstring curls and quadriceps exercises are appropriate.
- Closed chain exercised like squats should be performed with the first MTP joint maintained in plantarflexion in a toe spica.
- Exercise performance should be supervised to ensure that the flexor and/or extensor hallucis longus muscles are not activated.
- Exercises such as the lunge that involve extreme first MTP dorsiflexion are contraindicated at this stage.

Activation of Primary Muscles Involved

- Starting with passive and then active first MTP plantarflexion, the patient starts to activate his or her flexor hallucis longus in open chain exercises.
- Over time, open chain first MTP dorsiflexion using the extensor hallucis longus is initiated, taking take to avoid impingement and avoid forcing the joint into excessive dorsiflexion.

Sensorimotor Exercises

- Hydrotherapy and whirlpools are useful adjuncts. Water aerobics and walking in the pool can be initiated.

Open and Closed Kinetic Chain Exercises

- Towel crunches are commenced for the toe flexors and extensors (Figure 45-6). Marble or rubber band pickups,

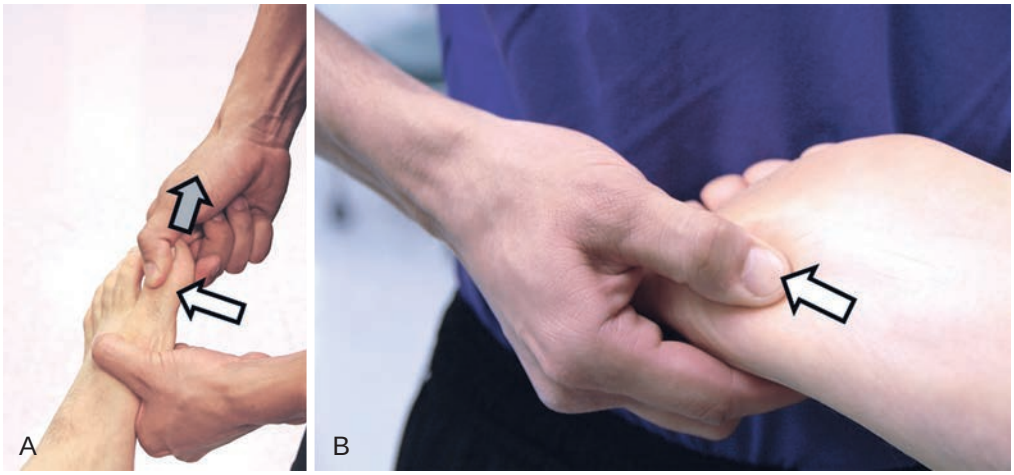

FIGURE 45-5. Manual therapy techniques may involve distraction (*gray arrow,* **A**) and anterior-posterior glides (*white arrow,* **A**) of the first MTP joint. Manual therapy to facilitate distal sesamoid glides (*white arrow,* **B**) may also be used to improve first MTP joint dorsiflexion.

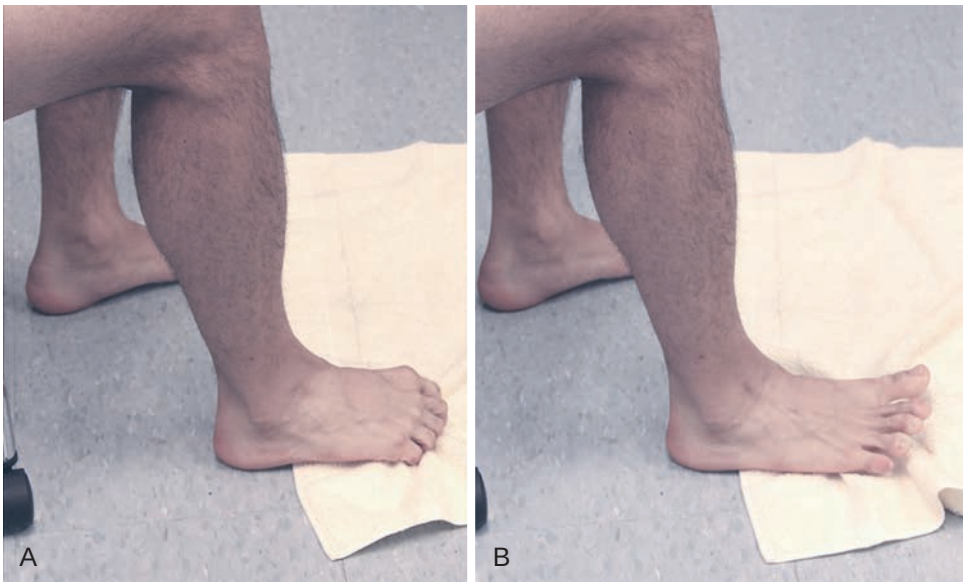

FIGURE 45-6. Exercises like towel crunches can be used to promote full range active first MTP joint dorsiflexion (**B**) and plantarflexion (**A**).

in which the patient is asked to pick up marbles from the floor and put them into a bowl using their toes, can also be instituted for the same purpose.
- Ankle circles and ankle pumps (OKC ankle exercises) are used to reduce swelling and maintain range of motion.
- As in Phase I, resisted CKC exercises are limited to the contralateral limb.
- Resisted OKC exercises of the proximal muscles (hamstrings, quadriceps, and glutei) are recommended.
- As pain and swelling subside, the patient is allowed to transition to weight bearing as tolerated, and finally to full weight bearing.

Techniques to Increase Muscle Strength, Power, and Endurance

- OKC resisted ankle plantarflexion using a Thera-Band can be initiated (Figure 45-7). Ankle dorsiflexion-plantarflexion and inversion-eversion can be performed with Thera-Band. Progression involves increasing the number of repetitions and sets, and also increasing the stiffness of the Thera-Band used.
- With the foot protected in a stiff-soled shoe, carbon graphite shoe insert, or Morton's extension, the patient can start using a stationary bicycle with instructions to avoid excessive first MTP dorsiflexion.
- Seat height needs to be adjusted and the main goal is to increase lower extremity muscle endurance while protecting the first MTP joint from excessive dorsiflexion.

Neuromuscular Dynamic Stability Exercises

- When the patient can tolerate bilateral stance with equal weight bearing, dynamic neuromuscular exercises that involve standing on surfaces of varying stability and stiffness should be commenced.
- Bilateral activities such as squats and heel raises should be initiated in the pain-free range and progress to multiple repetitions over the full range.
- During these exercises, it is important to flag and correct asymmetry in exercise performance and weight bearing.

Functional Exercises

- One of the chief goals of Phase II is to restore pain-free ambulation.
- When the patient is able to sustain unilateral single limb stance (see balance and neuromuscular stability exercises), walking should be attempted.
- Pool walking may be used to help with graduated weight bearing.
- Overground or treadmill walking should be initiated with protective footwear and/or shoe inserts.
- Pain-free and symmetrical ambulation is the primary goal. As patient progresses, speed and duration can be increased.

Sport-Specific Exercises

- Sport-specific upper limb activities such as throwing can be resumed in Phase II.
- Any weight-bearing activity should be performed with protective footwear and/or shoe inserts.
- Sport- and position-specific tasks such as the three-point stance for defensive linemen will be incorporated in Phase III.

Milestones for Progression to the Next Phase

- Pain-free range of motion (60° first MTP dorsiflexion, measured passively with a goniometer) and pain-free weight bearing (standing and walking) serve as criteria for progression to Phase III (Return to Sport).

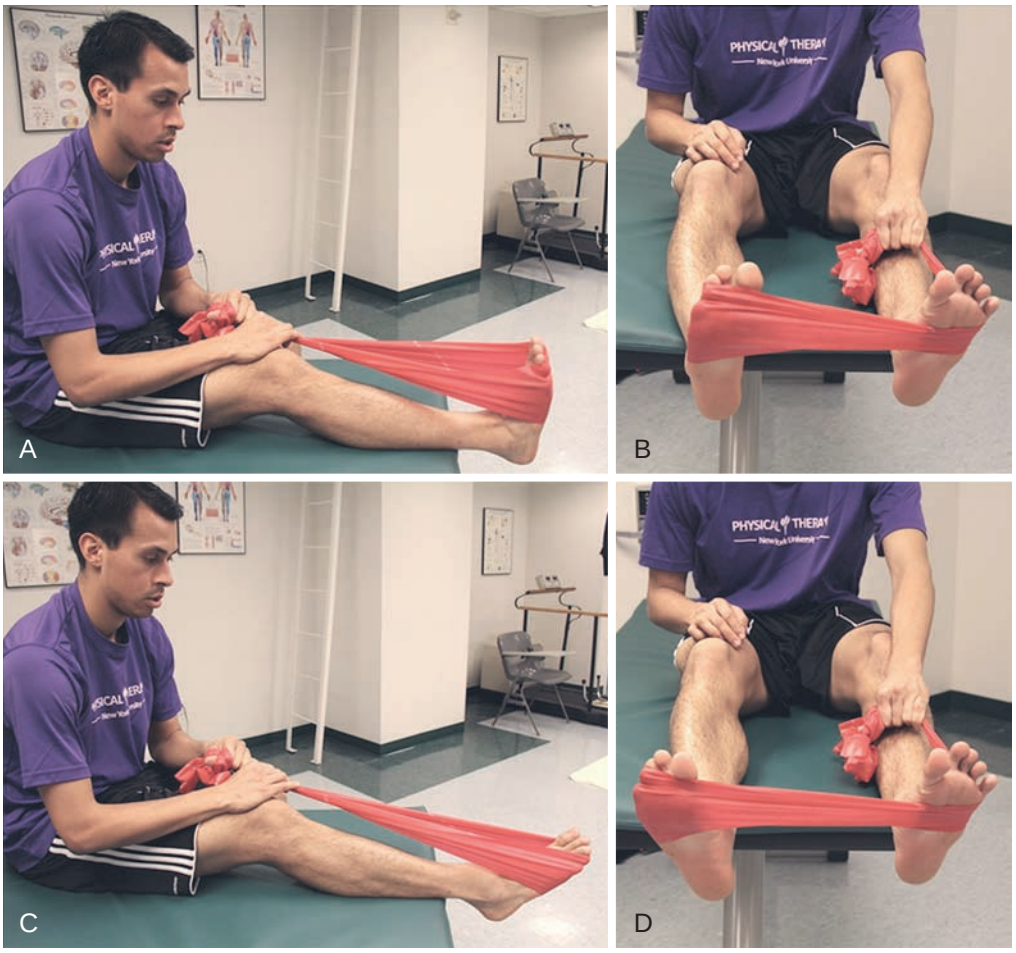

FIGURE 45-7. Open chain ankle dorsiflexion (**A**), plantarflexion (**B**), inversion (**C**), and eversion (**D**) using Thera-Band. Progression will involve increasing the number of repetitions, as well as sets and stiffness of the Thera-Band used.

Phase III (weeks 12 to 16): Return to Sport

- When the patient is able to walk without pain at the first metatarsophalangeal joint and demonstrates pain-free range of motion on clinical testing, they are ready to progress to Phase III.
- This phase may last 4 weeks to 3 months based on the severity and chronicity of the original injury, and demands of the sport and position he or she plays.

Protection

- Morton's extension or rigid sole shoes are used during high-demand activities.

Management of Pain and Swelling

- Ice, in combination with RICE if needed, is used to control pain and swelling, and is particularly useful to limit post-workout symptoms.

Techniques for Progressive Increase in Range of Motion

- Manual therapy, in the form of soft tissue and joint mobilizations, is used to ensure full range of motion and good tissue extensibility. In addition to glides and distraction at the first MTP joint, sesamoid mobilization may be employed to achieve full range of first MTP dorsiflexion.
- In addition to weight bearing and non–weight-bearing stretches for the gastrocnemius and soleus, a plantar fascia stretch may also be incorporated.
- Joint and soft tissue mobilization may be indicated to achieve full range of motion at proximal and contralateral lower extremity joints, including tarsometatarsal, talonavicular, subtalar, ankle, tibiofibular, knee, and hip joints.

Other Therapeutic Exercises

- As previously detailed, core, upper extremity and contralateral lower extremity strength training and stretching regiments should continue.

- In addition, weight-bearing closed chain exercises of the involved limb should be initiated.
- Lunges without and with additional resistance should be used. These are extremely provocative and the presence of pain and impingement should be monitored before and after each workout.

Activation of Primary Muscles Involved

- By Phase III, activation of great toe (flexor hallucis longus, extensor hallucis longus) and ankle muscles (gastrocnemius, soleus, peronei, tibialis anterior, tibialis posterior, flexor digitorum longus) should be symmetric and free from deficits.

Sensorimotor Exercises

- The patient should be able to walk barefoot without pain at the start of Phase III.
- Balance and proprioception training should begin with activities involving single limb stance (Figure 45-8). Activity-specific positions may need to be incorporated; for example, stork stance from martial arts training.
- More dynamic tasks such as the star excursion and balance test (SEBT) should be used, with cueing so the patient does not overuse the flexor hallucis longus muscle. Overuse of the flexor hallucis longus muscle will manifest as excessive flexion of the first MTP and/or interphalangeal joints. Single limb stance should be commenced in front of a mirror or with other visual feedback. Cues such as "relax the toe" should be used to prevent excessive use of the flexor hallucis longus.
- Appropriate activation of proximal muscles such as the hip rotators and abductors should be emphasized. In single limb stance, attention should be paid to maintaining proper form and balance (see Figure 45-8). Progression will involve increasing the duration (for example, three sets of 30 seconds each). Additionally balance can be challenged by presenting unstable surfaces and by adding dynamic activities (see Figure 45-8). During balance and proprioception training, a mirror or other visual feedback should be used to prevent overuse of arms, excessive trunk lean, dynamic knee valgus, and/or calcaneal pronation (see Figure 45-8).

Open and Closed Kinetic Chain Exercises

- In this phase, the patient should progress from walking to stair climbing. Stair ascent and descent place significant demands on the first MTP joint and are more challenging than straight-ahead gait.
- Bilateral graduated weight bearing in increasing amounts of first MTP dorsiflexion can be initiated using exercises like the heel raise.
- Progression involves performing single limb heel raises, first without then with additional free weights.
- When the patient can perform full range unilateral heel raises and negotiate stairs without pain, additional unilateral resisted exercises (lunges) can be instituted. Progression will include multidirectional lunges with added weights.

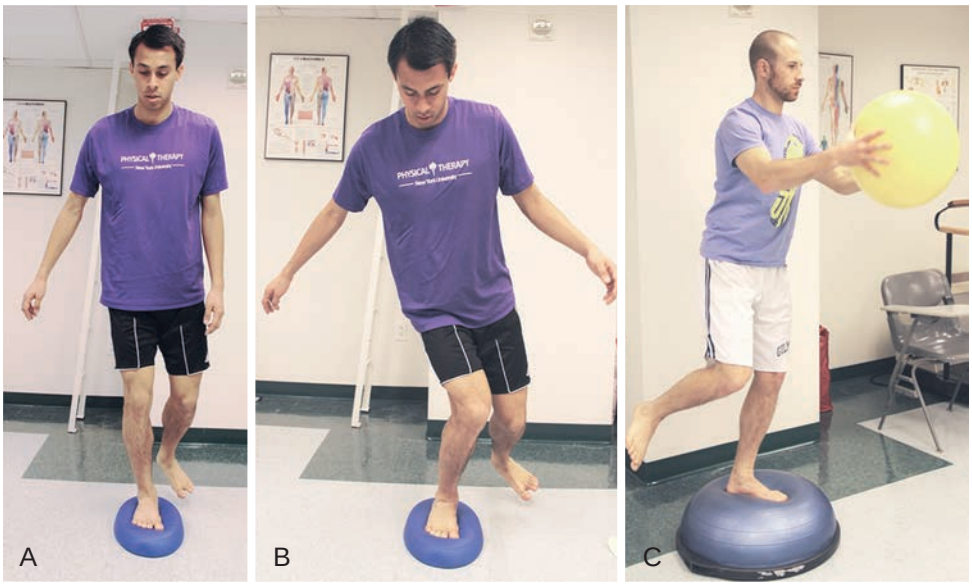

FIGURE 45-8. Single limb stance on a foam surface with good mechanics is depicted (**A**). Note the alignment of the knee over the second toe; the stance knee is not locked ("soft knee") and there is an absence of any trunk lean. Inability to maintain posture and balance in single limb stance (**B**) will manifest as excessive knee valgus, calcaneal pronation, first MTP flexion, trunk lean, and/or excessive use of arms for balance. Training to improve posture and balance in single limb stance starts with the patient barefoot on a stable surface, and progression involves increasing the duration, unstable surfaces (e.g., foam, BOSU ball), and dynamic activities (e.g., ball toss on BOSU ball) (**C**).

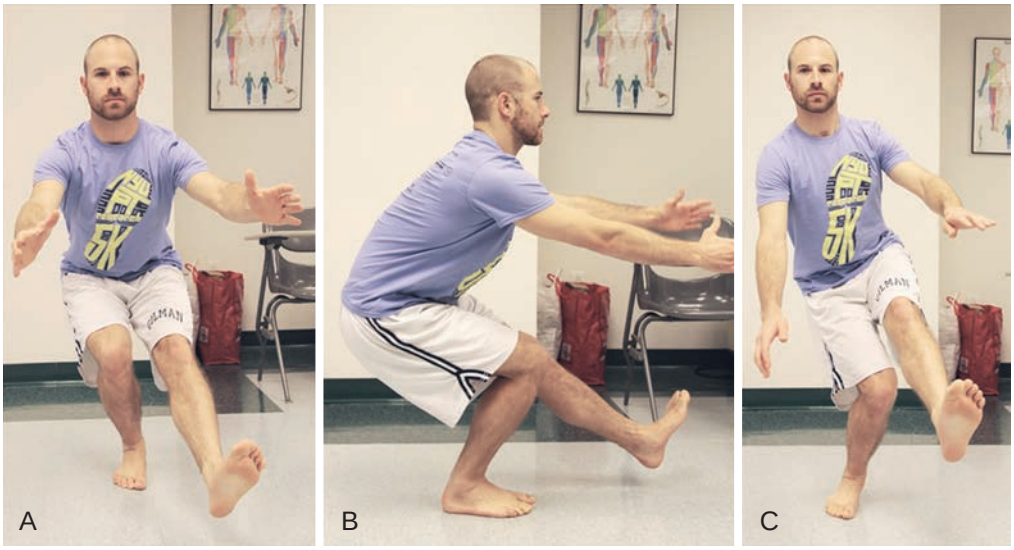

FIGURE 45-9. Single limb squats can be used in Phase III to promote closed kinetic chain function because they require activation of both proximal and distal muscles of the stance leg. Attention to good mechanics is crucial. In the frontal plane, note alignment of knee over second toe, hips and knees are level, no trunk lean is present (**A**). In the lateral view, the knee should be over the toes and arms extended (**B**). Markers of poor mechanics include excessive toe out, arch collapse, dynamic knee valgus, pelvic drop, and/or trunk lean (**C**).

- Single limb squats can also be useful in this phase (Figure 45-9).

Techniques to Increase Muscle Strength, Power, and Endurance

- See Open and Closed Kinetic Chain Exercises.

Neuromuscular Dynamic Stability Exercises

- Standing with balance and proprioception training, the patient should progress to performing more dynamic tasks such as single limb squats, single limb hops and agility drills (Figures 45-10 to 45-12).
- Progression should involve cutting and rapid changes in direction.

Plyometrics

- Eccentric exercises targeting the calf muscles in particular and the lower extremity in general are indicated.
- In athletes involved with sports such as gymnastics and martial arts, plyometrics are particularly important for

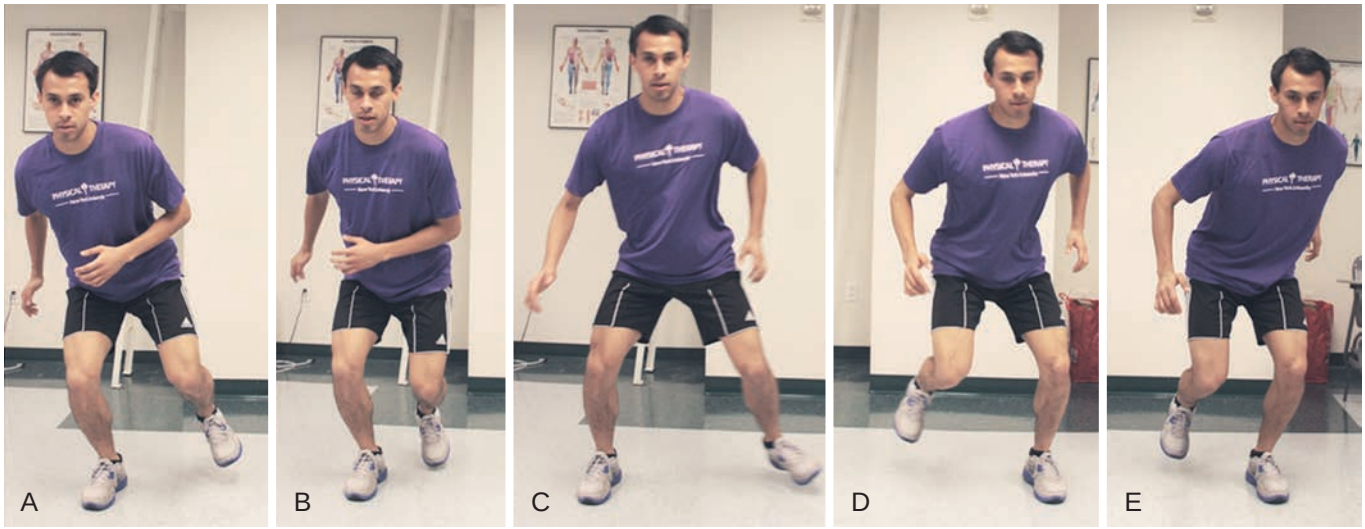

FIGURE 45-10. Drills such as the side shuffle should be used to regain agility. Panels A through E depict symmetrical performance and ideal form. Visual biofeedback using a mirror can be used to ensure good mechanics, reflected in symmetrical performance, absence of trunk lean, dynamic valgus, and arch collapse. Audio feedback in terms of curing the patient to the sound of footfalls can be used to encourage him or her to maintain a light and quick cadence.

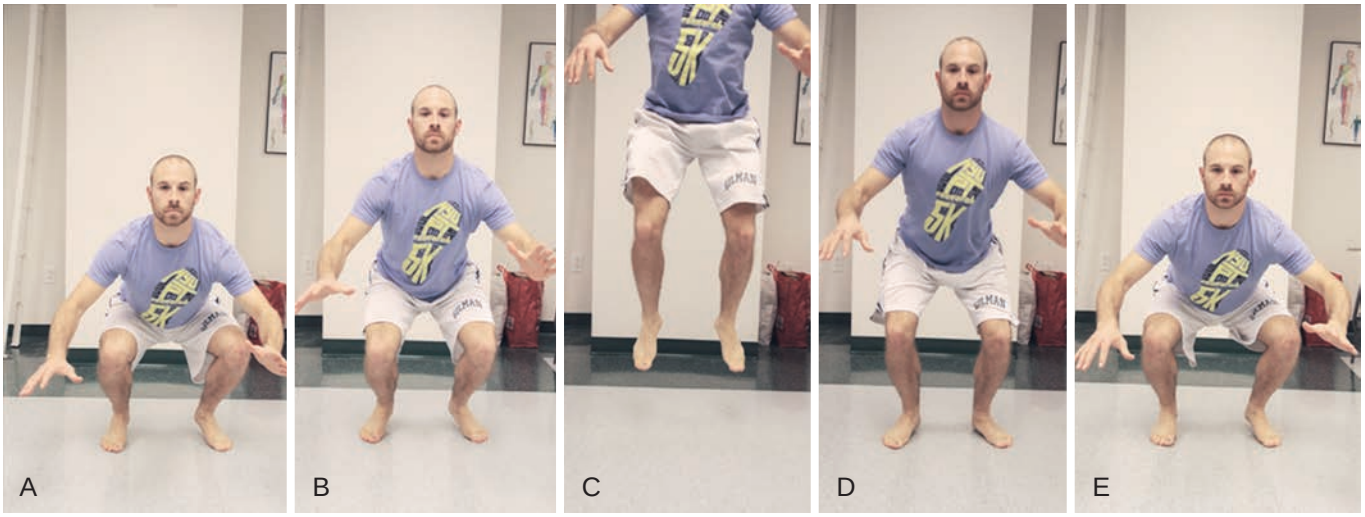

FIGURE 45-11. Return to sport (Phase III) should include sport-specific training such as jumping. Feet, knees, and hips should be symmetrical during takeoff (**A, B, C**) and landing (**D, E**).

proper technique and biomechanics during takeoff and landing.
- Motor learning and imagery techniques should be used to cue proximal muscles (core and hip muscles) and reduce the shock absorption and eccentric demand placed on distal extremity muscles like the flexor hallucis longus (e.g., the cue "pretend you're landing on marshmallows" is used to train landing in gymnasts and dancers).

Functional Exercises

- See Open and Closed Kinetic Chain Exercises and Sensorimotor and Neuromuscular Stability Exercises.

Sport-Specific Exercises

- For sports involving explosive starts and rapid changes in direction (baseball, football), agility drills incorporating these elements with are essential elements of sport-specific training.
- Additionally these drills should be performed on the playing surface with footwear used during competition to approximate realistic conditions.
- For activities involving jumping and landing (volleyball, dance), jumping drills with changes in direction should be included.

Tips and Guidelines for Transitioning to Performance Enhancement

- Prophylactic taping, the use of stiff-soled shoes (Figures 45-13 and 45-14) or Morton's extensions may facilitate the transition to performance.
  - Post-game ice and maintenance of range of motion through joint mobilization should be used to facilitate recovery.

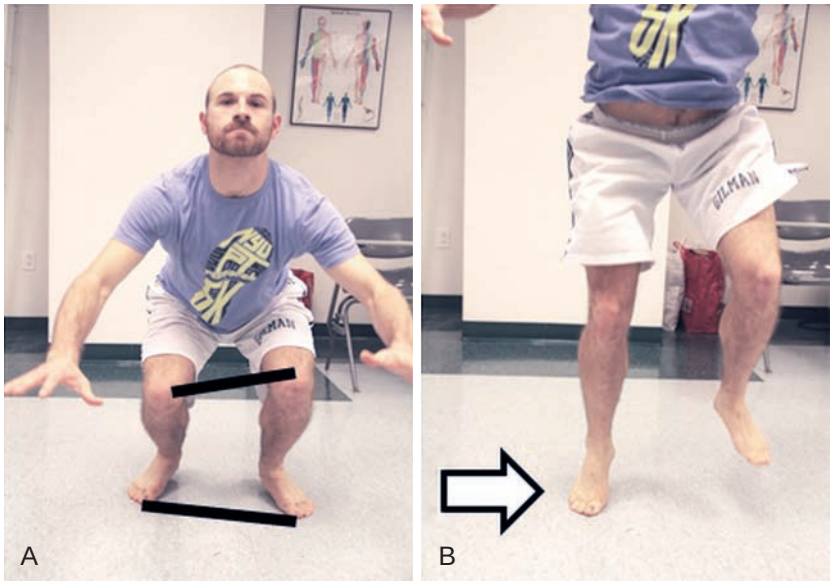

FIGURE 45-12. A, Poor mechanics during takeoff may manifest as an asymmetrical or staggered stance, which in turn may lead to asymmetry or obliquity at the knees and/or hips. **B,** Poor mechanics during landing may result in one limb contacting the floor before the other.

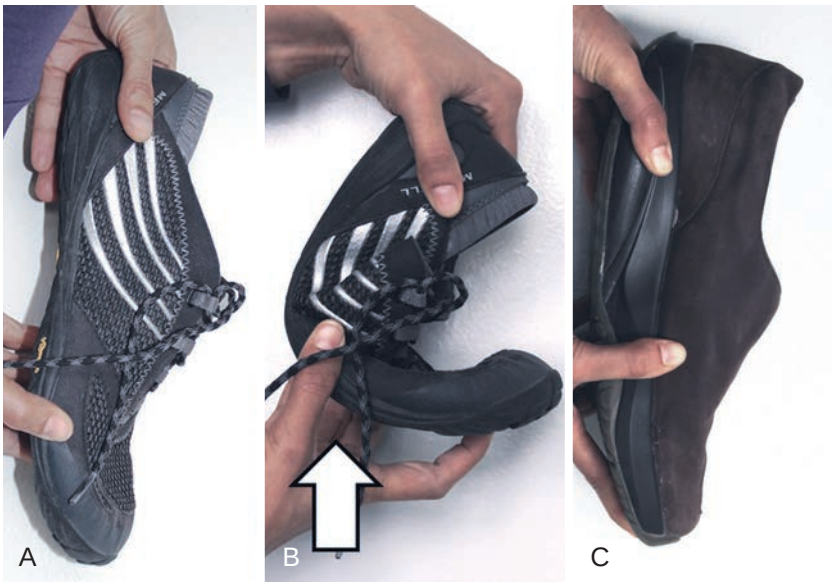

FIGURE 45-13. Athletic shoe (**A**) with high toe-break flexibility (**B**). Walking shoe with minimal toe-break flexibility (**C**).

Performance Enhancement and Beyond Rehabilitation: Training/ Trainer and Optimization of Athletic Performance

- Surveillance for impingement and/or osteochondral injuries should continue after return to performance.
- Communication with patient and trainer is essential to set realistic expectations for recovery and return to sport.
- Upon complete resolution of symptoms, taping and shoe inserts can be discontinued.

FIGURE 45-14. Athletic shoe (**A**) with high torsional flexibility (**B**).

Specific Criteria for Return to Sports Participation: Tests and Measurements

- Pain-free and full range of motion
- Pain free during weight bearing activities
- Complete resolution of symptoms

Evidence

Limited objective data are available to guide the nonsurgical management of turf toe. The following annotated bibliography highlights recent comprehensive reviews that present retrospective data and/or clinical cases.

Chinn L, Hertel J: Rehabilitation of ankle and foot injuries in athletes. *Clin Sports Med* 29(1):157–167, 2010.

This review comprehensively covers current nonsurgical options available for foot and ankle injuries, including turf toe. (Level IV evidence)

Coughlin MJ, Kemp TJ, Hirose CB: Turf toe: Soft tissue and osteocartilaginous injury to the first metatarsophalangeal joint. *Phys Sportsmed* 38(1):91–100, 2010.

This review highlights the importance of identifying and managing osteocartilaginous injury in turf toe. (Level IV evidence)

Maglaya CL, et al: Return to division 1A football following a metatarsophalangeal joint dorsal dislocation. *NAJSPT* 5(3):131–142, 2010.

This case study follows the rehabilitation protocol of a Division 1A football player following a turf toe injury. (Level IV evidence)

McCormick JJ, Anderson RB: The great toe: failed turf toe, chronic turf toe, and complicated sesamoid injuries. *Foot Ankle Clin* 14(2):135–150, 2009.

McCormick JJ, Anderson RB: Rehabilitation following turf toe injury and plantar plate repair. *Clin Sports Med* 29(2):313–323, ix, 2010.

This recent review provides an overview of the rehabilitation of turf toe as well as provides specific examples of interventions used in current clinical practice. (Level IV evidence)

Nihal A, Trepman E, Nag D: First ray disorders in athletes. *Sports Med Arthrosc* 17(3):160–166, 2009.

This review emphasizes the role of relative rest, activity modification, and insoles in the rehabilitation of individuals with turf toe injuries. (Level IV evidence)

Multiple Choice Questions

QUESTION 1. For Grade 1 turf toe injuries, which of the following is appropriate?

A. Immobilization in a toe spica in the acute postinjury phase
B. Manual therapy in the form of soft tissue and joint mobilization is the modality of choice in the acute postinjury phase.
C. Immobilization with taping and early progression to Phase II are the main goals in the acute postinjury phase.
D. Manual therapy should only be instituted after swelling subsides.

QUESTION 2. For a patient with a Grade II turf toe sprain, criteria for progression from Phase II to Phase III are:

A. Duration since injury—progress to Phase III in 4 weeks
B. Duration since injury—progress to Phase III in 2 weeks
C. Pain free full range of motion
D. Pain free on full weight bearing

QUESTION 3. A Morton's extension or turf toe plate is used to prevent

A. excessive dorsiflexion of the first metatarsophalangeal joint.
B. excessive plantarflexion of the first metatarsophalangeal joint.
C. excessive impact and cushion plantar sesamoids.
D. arch collapse by complementing the windlass effect.

Answer Key

QUESTION 1. Correct answer: **C** (see Phase I)

QUESTION 2. Correct answer: **D** (see Phase III)

QUESTION 3. Correct answer: **A** (see Phase II)
